#### **Summary**

Synthetic biology builds upon the techniques and successes of genetics, molecular biology, and metabolic engineering by applying engineering principles to the design of biological systems. The field still faces substantial challenges, including long development times, high rates of failure, and poor reproducibility. One method to ameliorate these problems would be to improve the exchange of information about designed systems between laboratories. The *Synthetic Biology Open Language* (SBOL) has been developed as a standard to support the specification and exchange of biological design information in synthetic biology, filling a need not satisfied by other pre-existing standards. This document details version 2.0 of SBOL, introducing a standardized format for the electronic exchange of information on the structural and functional aspects of biological designs. The standard has been designed to support the explicit and unambiguous description of biological designs by means of a well defined data model. The standard also includes rules and best practices on how to use this data model and populate it with relevant design details. The publication of this specification is intended to make these capabilities more widely accessible to potential developers and users in the synthetic biology community and beyond.

# 1 Purpose

Synthetic biology builds upon the techniques and successes of genetics, molecular biology, and metabolic engineering by applying engineering principles to the design of biological systems. These principles include standardization, modularity, and design abstraction. The field still faces substantial challenges, including long development times, high rates of failure, and poor reproducibility. A common factor of these challenges is the exchange of information about designed systems between laboratories. When designing a synthetic system, synthetic biologists need to exchange information about multiple types of molecules and their expected behavior in the design. Furthermore, there are often multiple degrees of separation between a specified nucleic acid sequence (e.g., a sequence that encodes an enzyme or transcription factor) and the molecular interactions that a designer intends to result from said sequence (e.g., chemical modification of metabolites or regulation of gene expression), yet these different perspectives need to be connected together in the engineering of biological systems.

The *Synthetic Biology Open Language* (SBOL) has been developed as a standard to support the specification and exchange of biological design information in synthetic biology, filling a need not satisfied by other pre-existing standards. Previous nucleic acid sequence description formats lack key capabilities. For example, simple sequence encoding formats such as FASTA encode almost nothing about design rationale. More sophisticated formats such as GenBank and Swiss-Prot support a flat annotation of sequence features that is well suited to the description of natural systems, but is unable to represent the multi-layered design structure common to engineered systems. Figure 1 shows the relationship of selected prior sequence description formats to SBOL 1.1 and SBOL 2.0. Modelling languages, such as the Systems Biology Markup Language (SBML) Finney et al. (2006) can be used represent biological processes, but are not sufficient to represent the associated nucleotide or amino acid sequences. Synthetic biology needs a structured standard that defines how to represent relevant molecules and their functional roles within a designed system, standardized rules on how such information is encoded in a file format, and software libraries to enable the exchange of such data between participating laboratories and as part of the publication process.

To help address these challenges, SBOL introduces a standardized format for the electronic exchange of information on the structural and functional aspects of biological designs. The standard has been designed to support the explicit and unambiguous description of biological designs by means of a well defined data model. The standard further describes the rules and best practices on how to use this data model and populate it with relevant design details. SBOL uses existing Semantic Web practices and resources, such as *Uniform Resource Identifiers* (URIs) and ontologies, to unambiguously identify and define genetic design elements. The definition of the data model and associated format, the rules on the addition of data within the format and the representation of this in electronic data files are intended to make the SBOL standard a useful means of promoting global data exchange between laboratories and between software programs.

This document details version 2.0 of SBOL. The previous version 1.1 of the SBOL standard focused on representing the structural aspects of genetic designs. Users of the standard were able to exchange information on DNA designs, but they could not represent molecules other than DNA or the functional aspects of designs beyond DNA sequence features. The SBOL 2.0 data model defined in this specification extends the version 1.1 data model to provide for the most pressing data exchange needs identified by the SBOL community. In particular, the extended data model can:

- Represent non-DNA structural components of a biological design, including RNA, proteins, small molecules and other physical components.
- Describe the behavioral aspects of a biological design, such as the intended or expected molecular interactions, and link to mathematical models written in other standards
- Associate structure and function so that a single design can be understood in terms of its structure, behavior, or both.
- Support rich annotation of biological designs, so that classes of design data that are not explicitly covered by this specification can be safely exchanged

Section 1 Purpose Page 3 of 89

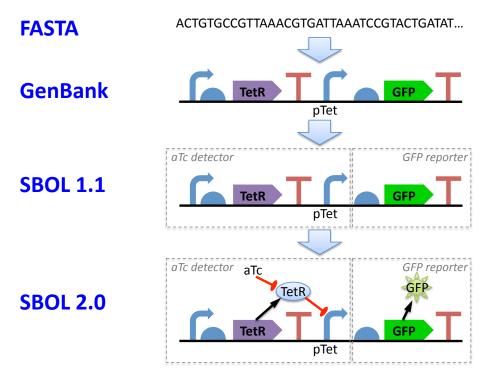

Figure 1: SBOL 2.0 extends prior sequence description formats to represent both the structure and function of a genetic design in a modular, hierarchical manner.

Taken together, these extensions enable SBOL to support the description and exchange of hierarchical, modular representations of both the intended structure and function of designed biological systems.

While the ultimate goal of SBOL is to describe synthetic biological designs such that they can be reproduced in the lab with a high degree of fidelity, SBOL 2.0 does not yet provide a complete catalog of the different classes of data that are necessary to achieve this goal. For example, SBOL 2.0 does not yet include data on environmental and host context, or details on how the performance of a design is measured. To enable progress towards capturing these types of data, SBOL 2.0 provides an annotation mechanism that allows SBOL to be easily extended (see Section 7.11). Three scenarios are envisaged for extending SBOL:

- Critical data related to the reproducibility of designs. These include what growth media was used, what temperature the organisms were grown at, or where the recombinant DNA was integrated into the host genome or a plasmid.
- Tool specific data. These could include tool settings specific to the design that is being loaded, such as which windows are to be opened or which settings are to be initialized. Tool makers could also include encrypted proprietary information related to a company or client in an extension.
- Data that are non-essential for reproducibility but are nevertheless useful to many users. There are many cases where specific communities of users require data that cannot be explicitly represented using the SBOL data model. These include data on visualization, evolutionary stability, or other.

The extension mechanism is therefore a critical part of SBOL 2.0 and will allow others in the community to incorporate their own custom data into SBOL files and contribute to community efforts to expand the scope of SBOL

The SBOL 2.0 specification also adds a number of measures to simplify adoption and validation of compatibility with the standard. First, unlike the SBOL 1.1 specification, the SBOL 2.0 specification explicitly incorporates the primary

Section 1 Purpose Page 4 of 89

Section

serialization format for its data model to better show how the standard can be used. Second, the specification includes a set of validation rules for determining the compatibility of a document with SBOL 2.0, most of which are machine-verifiable. Finally, the specification includes a set of recommended best practices that can allow software tools to take best advantage of the standard and effectively exchange data.

In addition, care has been taken to ensure that SBOL 2.0 is backwards-compatible with previous versions. While the changes made in SBOL 2.0 do mean that a SBOL 1.x file is not a valid SBOL 2.0 file, there does exist a direct mapping from the SBOL 1.x data model to the SBOL 2.0 data model, making it possible to automatically convert any SBOL 1.x file to an SBOL 2.0 file. Since SBOL 2.0 can encode all data previously encoded in SBOL 1.1, developers are encouraged to upgrade their SBOL 1.1 compliant software tools to use SBOL 2.0 software libraries.

Lastly, the SBOL standard has been developed in collaboration between both "wet" bench scientists and "dry" scientific modelers and software developers that are active within the synthetic biology community. As before with SBOL version 1.1, this open community has met to discuss and agree upon the data exchange needs that version 2.0 of the SBOL standard is intended to address. These discussions have informed the efforts of developers within the community to produce a SBOL 2.0 specification after several rounds of proposal and revision. This specification has been evaluated by the community for its ability to represent a wide range of synthetic biology designs and share these designs between different laboratories. This specification has also informed the development of software libraries that implement the standard, and software tools that employ the standard by means of these libraries, thereby providing further testing of SBOL 2.0. The publication of this specification is intended to make these capabilities more widely accessible to potential developers and users in the synthetic biology community and beyond.

Section 1 Purpose Page 5 of 89

# 2 Relation to other BBF RFCs

BBF RFC 107 replaces BBF RFC 87 (the SBOL 1.1 standard).

BBF RFC 107 updates BBF RFC 30 (RDF-based framework for synthetic biology data), as it proposes a standard conforming to BBF RFC 30.

BBF RFC 107 also implicitly supersedes the previously replaced BBF RFC 84 (SBOL 1.0, replaced by BBF RFC 87) and BBF RFC 31 (PoBoL, replaced by BBF RFC 84).

# 3 Copyright and License Statement

# 4 A Brief History of SBOL

The SBOL effort was kickstarted in 2006 with the goal of developing a data exchange standard for genetic designs. Herbert Sauro (University of Washington) secured a modest grant from Microsoft in the field of computational synthetic biology, which was used to fund the initial meeting in Seattle on April 26-27, 2008. This workshop was organized by Herbert Sauro, Sean Sleight, and Deepak Chandran, and included talks by Raik Gruenberg, Kim de Mora, John Cumbers, Christopher Anderson, Mac Cowell, Jason Morrison, Jean Peccoud, Ralph Santos, Andrew Milar, Vincent Rouilly, Mike Hucka, Michael Blinov, Lucian Smith, Sarah Richardson, Guillermo Rodrigo, Jonathan Goler, and Michal Galdzicki.

Michal's early efforts were instrumental in making SBOL successful. As part of his doctoral work, Mike led the development of PoBol, as SBOL was originally known. He organized annual workshops from 2008 to 2011 and kept the idea of developing a genetic design standard alive. The original SBOL 1.0 was developed by a small group of dedicated researchers calling themselves the Synthetic Biology Data Exchange Working Group, meeting at Stanford in 2009 and Anaheim, CA in 2010. During the Anaheim meeting, the community decided to write a letter to Nature Biotechnology highlighting the issue of reproducibility in synthetic biology. This letter was initiated by Jean Peccoud and submitted by participants of the Anaheim meeting, including Deepak Chandran, Douglas Densmore, Dmytriv, Michal Galdzicki, Timothy Ham, Cesar Rodriquez, Jean Peccoud, Herbert Sauro, and Guy-Bart Stan. The overall pace of development quickened when several new members joined at the next workshop in Blacksburg, Virginia on January 7-10, 2011. This early work was also supported by an STTR grant from the National Institute of Health (NIH #1R41LM010745 and #9R42HG006737, from 2010-13) in collaboration with Clark & Parsia, LLC (Co-PIs: John Gennari and Evren Sirin). New members included Cesar Rodriguez, Mandy Wilson, Guy-Bart Stan, Chris Myers, and Nicholas Roehner.

The SBOL Developers Group was officially established at a meeting in San Diego in June 2011. Rules of governance were established, and the first SBOL editors were elected: Mike Galdzicki, Cesar Rodriguez, and Mandy Wilson. At our next meeting in Seattle in January 2012, Herbert Sauro was elected the SBOL chair, and two new editors were added: Matthew Pocock and Ernst Oberortner. New developers joining at these workshops included several representatives from industry, Kevin Clancy, Jacob Beal, Aaron Adler, and Fusun Yaman Sirin. New members hailing from Newcastle University included Anil Wipat, Matthew Pocock, and Goksel Misirli.

Development of the first software library (libSBOLj) based on the SBOL standard was initiated by Allan Kuchinsky, a research scientist from Agilent, at the 2011 meeting. By the time of the 2012 meeting, the first data exchange between software tools using SBOL was conducted when a design was passed from Newcastle University's VirtualParts Repository to Boston University's Eugene tool, and finally to University of Utah's iBioSim tool.

SBOL 1.0 was officially released in October 2011. In March 2012, SBOL 1.1 was released, the version that this document replaces. SBOL 1.1 did not make any major changes, but provided a number of small adjustments and clarifications, particularly around the annotation of sequences. Multi-institutional data exchange using SBOL 1.1 was later demonstrated in Nature Biotechnology Galdzicki et al. (2014).

While SBOL 1.1 had a number of significant advantages over the GenBank representation of DNA sequences, such as representing hierarchical organization of DNA components, it was still limited in other respects. The major topic of discussion at the 8th SBOL Workshop at Boston University in November 2012 was how to address these shortcomings through extensions. Several extensions were discussed at this meeting, such as a means to describe genetic regulation, which later became important classes in the current 2.0 specification.

A general framework for SBOL 2.0 emerged at the 9th SBOL workshop at Newcastle University in April 2013. Subsequently, Nicholas Roehner, Matthew Pocock, and Ernst Oberortner drafted a proposal for SBOL 2.0, and Nicholas presented this proposal at the SEED conference in Los Angeles in July 2014 Roehner et al. (2015). The proposed 2.0 data model was discussed over the course of the 10th, 11th, and 12th workshops. The actual specification document you are now reading was drafted at the 13th workshop in Wittenberg, Germany by the authors. The SBOL 2.0 data model presented here is essentially the result of these meetings and ongoing discussions conducted through the SBOL Developers mailing lists.

Section

The Computational Modeling in Biology Network (COMBINE) holds regular workshops where synthetic biologists and systems biologists can work toward a common goal of integrating biological knowledge through inter-operable and non-overlapping data standards. In April of 2014, several SBOL Developers attended a COMBINE workshop and then proposed that SBOL join this larger standards community. The proposal passed and SBOL workshops have been co-located with COMBINE meetings since the 11th workshop at the University of Southern California in August 2014.

Current development of this SBOL 2.0 specification is funded in large part by a grant from the National Science Foundation (DBI-1355909 and DBI-1356041). This document and the supporting software libraries are due in no small part to this support. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

# 5 SBOL Specification Vocabulary

#### 5.1 Term Conventions

This document indicates requirement levels using the controlled vocabulary specified in IETF RFC 2119 and reiterated in BBF RFC 0. In particular, the key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119.

- The words "MUST", "REQUIRED", or "SHALL" mean that the item is an absolute requirement.
- The phrases "MUST NOT" or "SHALL NOT" mean that the item is an absolute prohibition.
- The word "SHOULD" or the adjective "RECOMMENDED" mean that there might exist valid reasons in particular circumstances to ignore a particular item, but the full implications need to be understood and carefully weighed before choosing a different course.
- The phrases "SHOULD NOT" or "NOT RECOMMENDED" mean that there might exist valid reasons in particular circumstances when the particular behavior is acceptable or even useful, but the full implications needs to be understood and the case carefully weighed before implementing any behavior described with this label.
- The word "MAY" or the adjective "OPTIONAL" mean that an item is truly optional.

#### 5.2 SBOL Class Names

SBOL defines the following "top-level" and dependent classes:

Collection: Represents a user-defined container for organizing a group of SBOL objects.

*ComponentDefinition*: Describes the structure of designed entities, such as DNA, RNA, and proteins, as well as other entities they interact with, such as small molecules or environmental properties.

- Component: Pointer class. Incorporates a child ComponentDefinition by reference into exactly one parent ComponentDefinition. Represents a specific occurrence or instance of an entity within the design of a more complex entity. Because the same definition might appear in multiple designs or multiple times in a single design, a single ComponentDefinition can have zero or more parent ComponentDefinitions, and each such parent-child link requires its own, distinct Component.
- Location: Specifies the base coordinates and orientation of a genetic feature on a DNA or RNA molecule or a residue or site on another sequential macromolecule such as a protein.
- SequenceAnnotation: Describes the Location of a notable sub-sequence found within the Sequence of a ComponentDefinition. Can also link to and effectively position a child Component.
- SequenceConstraint: Describes the relative spatial position and orientation of two Component objects that are contained within the same ComponentDefinition.

GenericTopLevel: Represents a data container that can contain custom data added by user applications.

*Model*: Links to quantitative or qualitative computational models that might be used to predict the functional behavior of a biological design.

*ModuleDefinition*: Describes a "system" design as a collection of biological components and their functional relationships.

■ FunctionalComponent: Pointer class. Incorporates a child ComponentDefinition by reference into exactly one parent ModuleDefinition. Represents a specific occurrence or instance of an entity within

Section 5.2 SBOL Class Names

the design of a system. Because the same definition might appear in multiple designs or multiple times in a single design, a single ComponentDefinition can have zero or more parent ModuleDefinitions, and each such parent-child link requires its own, distinct FunctionalComponent.

- Interaction: Describes a functional relationship between biological entities, such as regulatory activation or repression, or a biological process such as transcription or translation.
- MapsTo: When a design (ComponentDefinition or ModuleDefinition) includes another design as a sub-design, the parent design might need to refer to a ComponentInstance (either a Component or FunctionalComponent) in the sub-design. In this case, a MapsTo needs to be added to the instance for the sub-design, and this MapsTo needs to link between the ComponentInstance in the sub-design and a ComponentInstance in the parent design.
- Module: Pointer class. Incorporates a child ModuleDefinition by reference into exactly one parent ModuleDefinition. Represents a specific occurrence or instance of a subsystem within the design of a larger system. Because the same definition in multiple designs or multiple times in a single design, a single ModuleDefinition can have zero or more parent ModuleDefinitions, and each such parentchild link requires its own, distinct Module.
- Participation: Describes the role that a Functional Component plays in an Interaction. For example, a transcription factor might participate in an Interaction as a repressor or as an activator.

Sequence: Generally represents a contiguous series of monomers in a macromolecular polymer such as DNA, RNA, or protein. A Sequence can also encode the atoms and bonds of a molecule with non-linear structure (see Section 7.6).

# 6 Overview of SBOL

Synthetic biology designs can be described using:

- Structural terms, e.g., a set of annotated sequences or information about the chemical makeup of components.
- Functional terms, e.g., the way that components might interact with each other and the overall behavior of a design.

In broad strokes, the prior SBOL 1.1 standard focused on conveying physical, structural information, whereas SBOL 2.0 expands the scope to include functional aspects as well. The physical information about a designed genetic construct includes the order of its constituents and their descriptions. Specifying the exact locations of these constituents and their sequences allow genetic constructs to be defined unambiguously and reused in other designs. SBOL 2.0 extends SBOL 1.1 in several ways: it extends physical descriptions to include entities beyond DNA sequences, and it supports functional descriptions of designs.

As an example, consider the design of an expression cassette, such as the one found in the plasmid pUC18 Norrander et al. (1983). This device is designed to detect successful versus unsuccessful molecular cloning. As an overall system, the device is designed to grow either blue-colored (unsuccessful) or white-colored (successful) colonies in the presence of IPTG and the chemical X-gal. Internally, the device has a number of parts, including a promoter, the lac repressor binding site, and the lacZ coding sequence. These parts have specific component-level interactions with IPTG and X-gal, as well as native host gene products, transcriptional machinery and translational machinery that collectively cause the desired system-level behavior.

Knowledge of how such a device functions within the context of a host and how it might be adapted to new experimental applications has generally been passed on through working with fellow scientists or reading articles in papers and books. But there has been no systematic way to communicate the integration of sequences with functional designs, so users typically have had to look in many different places to develop an understanding of a system. The SBOL 2.0 standard allows designers to describe these functional characteristics and connect them to the physical parts and sequences that make up the design.

SBOL 2.0 includes two main classes that match the structural/functional distinction above:

- The ComponentDefinition object describes the physical aspects of the designed system, such as its DNA or RNA sequences, and the physical relationships among sub-components, as when one sequence contains another as a sub-sequence.
- The ModuleDefinition object describes interactions of the designed system, such as specific binding relationships and repression and activation relationships.

Figure 2 shows a simplified view of these classes, as well as other helper classes in SBOL. To continue with the pUC18 example, the description would begin with a top-level ModuleDefinition. The ModuleDefinition specifies the structural elements that make up the cassette by referencing a number of ComponentDefinition objects. These would include the DNA component for the promoter and the small molecule component for IPTG, for example. The ComponentDefinition objects can be organized hierarchically. For example, the plasmid ComponentDefinition might reference ComponentDefinitions for the promoter, coding sequence, etc. Each ComponentDefinition object can also include the actual Sequence information (if available), as well as SequenceAnnotation objects that identify the locations of the promoters, coding sequences, etc., on the Sequence. In order to specify functional information, the ModuleDefinition can specify Interaction objects that describe any qualitative relationships among components, such as how IPTG and X-gal interact with the gene products. Finally, a ModuleDefinition object can point to a Model object that provides a reference to a complete computational model using a language such as SBML, CellML, Matlab, etc. Finally, all the of elements of the genetic design can be grouped together within a Collection.

Section

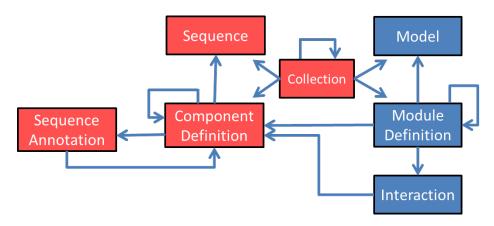

Figure 2: Main classes of information represented by the SBOL standard, and their relationships. Red boxes are classes from the SBOL 1.1 that focused on structure, whereas blue classes are some of the new classes that support the functional aspects of designs.

Whereas Figure 2 provides a broad overview of SBOL, Figure 3 provides a detailed, implementation-level overview of the class structure for the SBOL 2.0 data model. This figure relies on the semantics of the *Unified Modeling Language* (UML), which will be presented in more detail in the next section. Figure 3 distinguishes between *top level* classes, in green, and other supporting classes (note that Figure 2 also includes all of the top level classes). In Figure 3, dashed arcs represent "refersTo", whereas a solid arrow represents ownership. In UML, the meaning of ownership is that if a parent class is deleted, so are all of its owned children. Thus, a Collection does not own its ComponentDefinition objects, because these can stand on their own. All of the supporting classes (in orange) have to be owned by some top-level class, directly or indirectly.

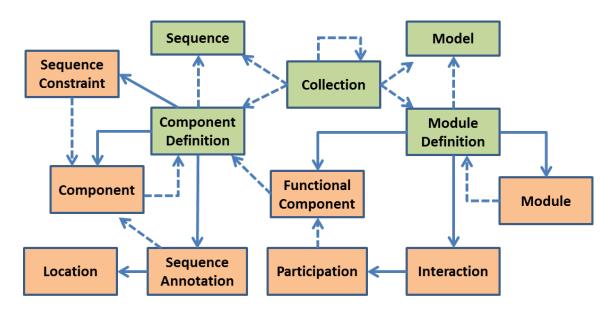

Figure 3: Main classes of information represented by the SBOL 2.0 standard, and their relationships. Green boxes are "top level" classes, while the other classes are in support of these classes. Solid arrows indicates ownership, whereas a dashed arrow indicates that one class refers to an object of another class.

Figure 3 additionally shows that when it is possible to incorporate a single object into multiple parents, we always incorporate that object by reference. We do not directly incorporate it by copy, because when an object is used many times, keeping many copies becomes spatially inefficient and difficult to maintain. Instead, each

11

Section

reference is handled by a pointer object. Pointers refer from a parent to a child. There are three distinct pointer classes: Component, Module, and FunctionalComponent. A Component points from a ComponentDefinition to a child ComponentDefinition, incorporating it by reference into the parent structure. A Module points from a ModuleDefinition to a child ModuleDefinition, likewise incorporating the child by reference into the parent system. Similarly, a parent ModuleDefinition on the functional side of a model might incorporate a child ComponentDefinition from the model's physical side by means of a FunctionalComponent reference. These three pointer classes allow the efficient reuse of definitions in multiple locations.

SBOL 2.0 provides a few helper classes. Location generalizes the positioning information from SBOL 1.1 to allow discontinuous ranges and cuts to be annotated. SequenceConstraint generalizes the relative positioning information among Components. There are also Participations, which allow Interaction objects to specify the roles of their participants while referencing the FunctionalComponents, so that these can stand on their own. Additionally, there is the MapsTo class (not shown), which enables connections to be made between Components and FunctionalComponents across various levels of the design hierarchy. The next section provides complete definitions and details for all of these classes.

There is one final, critical element of SBOL 2.0: its extension mechanism. This extension mechanism enables the storage of application specific information within an SBOL document. It is also intended to support the prototyping of data representations whose format is not yet a matter of consensus within the community. In particular, each SBOL entity can be annotated using the *Resource Description Framework* (RDF). Moreover, application specific entities in the form of RDF documents can be included as **GenericTopLevel** entities. SBOL libraries make these annotations and entities available to tools as generic properties and objects that are preserved during subsequent read and write operations.

# 7 SBOL Data Model

In this section, we describe the types of biological design data that can belong to an SBOL document and the relationships between these data types. The SBOL data model is specified using Unified Modeling Language (UML) 2.0 diagrams (OMG 2005). Subsections Section 7.1, Section 7.2, Section 7.3 review the basics of UML diagrams and explain the naming conventions and generic data types used in this specification. The remaining sections then describe the SBOL data model in detail. Complete SBOL examples and best practices when using the standard can be found in Section 9 and Section 11, respectively.

# 7.1 Understanding the UML Diagrams

The types of biological design data modeled by SBOL are commonly referred to as *classes*, especially when discussing the details of software implementation. Each SBOL class can be instantiated by many SBOL objects. These objects MAY contain data that differ in content, but they MUST agree on the type and form of their data as dictated by their common class. Classes are represented in UML diagrams as rectangles labeled at the top with class names.

Classes can be connected to other classes by association properties, which are represented in UML diagrams as arrows. These arrows are labeled with data cardinalities in order to indicate how many values a given association property can possess (see below). The remaining (non-association) properties of a class are listed below its name. Each of the latter properties is labeled with its data type and cardinality.

In the case of an association property, the class from which the arrow originates is the owner of the association property. A diamond at the origin of the arrow indicates the type of association. Open-faced diamonds indicate shared aggregation, in which the owner of the association property exists independently of its value. In the SBOL data model, the value of an association property MUST be a URI or set of URIs that refer to SBOL objects belonging to the class at the tip of the arrow.

By contrast, filled diamonds indicate composite aggregation, also known as a part-whole relationship, in which the value of the association property MUST NOT exist independently of its owner. In addition, in the SBOL data model, it is REQUIRED that the value of each composite aggregation property is a unique SBOL object (that is, not the value for more than one such property). Note that in all cases, composite aggregation is used in such a way that there SHOULD NOT be duplication of such objects.

All SBOL properties are labeled with one of several restrictions on data cardinality. These are:

- 1 REQUIRED, one: there MUST be exactly one value for this property.
- 0...1 OPTIONAL: there MAY be a single value for this property, or it MAY be absent.
- 0...\* unbounded: there MAY be any number of values for this property, including none.
- 1...\* REQUIRED, unbounded: there MAY be any number of values for this property, as long as there is at least one.
- $\blacksquare$   $n \dots *$  at least: there MUST be at least n values for this property.

Finally, classes can inherit the properties of other classes. Inheritance relationships are represented in UML diagrams as open-faced, triangular arrows that point from the inheriting class to the inherited class. Some classes in the SBOL data model cannot be instantiated as objects and exist only to group common properties for inheritance. These classes have italicized names and are known as abstract classes.

#### 7.2 Naming and Font Conventions

SBOL classes are named using upper "camel case," meaning that each word is capitalized and all words are run together without spaces, e.g. Identified, SequenceAnnotation. Properties, on the other hand, are named using lower camel case, meaning that they begin lowercase (e.g., identity) but if they consist of multiple words, all words

Section 7.3 Data Types

after the first begin with an uppercase letter (e.g., persistentIdentity).

Within the SBOL data model, each property is given a singular or plural name in accordance with its data cardinalities. The forms of these names follow the usual rules of English grammar. For example, sequenceAnnotation is the singular form of sequenceAnnotations.

SBOL properties are always given singular names, however, when SBOL objects are serialized (using *Resource Description Framework* (RDF) as described in Section 10). This is because the SBOL data model does not contain classes that correspond directly to the RDF elements that group other elements into ordered or unordered sets. Consequently, if an SBOL property has multiple values, then it is serialized as multiple property entries, each with a singular name and a single value. For example, if an SBOL property has five values, then its serialization contains five RDF triples, each with a singular predicate name and one of the five values as its object.

#### 7.3 Data Types

When SBOL use simple "primitive" data types such as Strings or Integers, these are defined as the following specific formal types:

- String: http://www.w3.org/TR/xmlschema11-2/#string

  Example: "LacI coding sequence"
- Double: http://www.w3.org/TR/xmlschema11-2/#double Example: 3.14159
- Boolean: http://www.w3.org/TR/xmlschema11-2/#boolean Example: true

The term literal is used to denote an object that can be any of the four types listed above. In addition to the simple types listed above, SBOL also uses objects with types *Uniform Resource Identifier* (URI) and *XML Qualified Name* (QName):

- URI: http://www.w3.org/TR/xmlschema11-2/#anyURI Example: http://www.partsregistry.org/Part:BBa\_J23119
- QName: http://www.w3.org/TR/xmlschema11-2/#QName

  Example: myapp:Datasheet where myapp="http://www.myapp.org/"

Note that, in compliance with RDF standards, URIs are generally serialized using an rdf:resource property, e.g.: rdf:resource="http://www.partsregistry.org/Part:BBa\_J23119"

It is important to realize that in RDF, a URI might or might not be a resolvable URL (web address). A URI is always a globally unique identifier within a structured namespace. In some cases, that name is also a reference to (or within) a document, and in some cases that document can also be retrieved (e.g., using a web browser).

#### 7.4 Identified

All SBOL-defined classes are directly or indirectly derived from the Identified abstract class. This inheritance means that all SBOL objects are uniquely identified using URIs that uniquely refer to these objects within an SBOL document or at locations on the World Wide Web.

As shown in Figure 4, the Identified class includes the following properties: identity, persistentIdentity, version, wasDerivedFrom, name, description, and annotations. The latter property is described separately in Section 7.11.

Section 7.4 Identified

When an SBOL resource reference takes the form of a URI, that URI can either be the value of an identity property or the value of a persistentIdentity property. If the URI is equal to the value of an identity property, then it is guaranteed to be unique, and it refers to precisely one SBOL object with that URI. If the URI is equal to the value of a persistentIdentity property, then it MAY refer to multiple SBOL objects that are different "versions" of each other. These objects SHOULD be compared to one another to determine which single object the URI resolves to (normally the most recent version - see Section 7.4). Throughout this document, when a URI is used to refer to an SBOL object, it could fall into either of these cases.

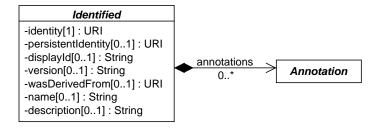

Figure 4: Diagram of the Identified abstract class and its associated properties

#### The identity property

The identity property is REQUIRED by all Identified objects and has a data type of URI. A given Identified object's identity URI MUST be globally unique among all other identity URIs. It is also highly RECOMMENDED that the URI structure follows the recommended best practices for compliant URIs specified in Section 11.2.

Although most SBOL properties are defined by SBOL and serialized with its namespace, the identity property is defined by the analogous RDF about property and is serialized with the RDF namespace as follows:

http://www.w3.org/1999/02/22-rdf-syntax-ns#about.

The use of about is expressly for the purpose of making SBOL compliant with pre-existing standards: when you see about in an SBOL document, you SHOULD interpret it as meaning identity.

#### The persistentIdentity property

The persistentIdentity property is OPTIONAL and has a data type of URI. This URI serves to uniquely refer to a set of SBOL objects that are different versions of each other.

An Identified object MUST be referred to using either its identity URI or its persistentIdentity URI.

#### The displayId property

The displayId property is an OPTIONAL identifier with a data type of String. This property is intended to be an intermediate between name and identity that is machine-readable, but more human-readable than the full URI of an identity.

If the <code>displayId</code> property is used, then its <code>String</code> value SHOULD be locally unique (global uniqueness is not necessary) and MUST be composed of only alphanumeric or underscore characters and MUST NOT begin with a digit.

#### The version property

The version property is OPTIONAL and has a data type of String. This property can be used to compare two SBOL objects with the same persistentIdentity.

Section 7 SBOL Data Model

Section 7.4 Identified

If the version property is used, then it is RECOMMENDED that version numbering follow the conventions of semantic versioning (http://semver.org/), particularly as implemented by Maven (http://maven.apache.org/). This convention represents versions as sequences of numbers and qualifiers that are separated by the characters "." and "-" and are compared in lexicographical order (for example, 1 < 1.3.1 < 2.0-beta). For a full explanation, see the linked resources.

#### The wasDerivedFrom property

The wasDerivedFrom property is OPTIONAL and has a data type of URI. An SBOL object with this property refers to another SBOL object or non-SBOL resource from which this object was derived.

If the wasDerivedFrom property of an SBOL object *A* that refers to an SBOL object *B* has an identical persistentIdentity, and both *A* and *B* have a version, then the version of *B* MUST precede that of *A*. In addition, an SBOL object MUST NOT refer to itself via its own wasDerivedFrom property or form a cyclical chain of references via its wasDerivedFrom property and those of other SBOL objects. For example, the reference chain "*A* was derived from *B* and *B* was derived from *A*" is cyclical.

#### The name property

The name property is OPTIONAL and has a data type of String. This property is intended to be displayed to a human when visualizing an Identified object.

If an Identified object lacks a name, then software tools SHOULD instead display the object's displayId or identity. It is RECOMMENDED that software tools give users the ability to switch perspectives between name properties that are human-readable and displayId properties that are less human-readable, but are more likely to be unique.

#### The description property

The description property is OPTIONAL and has a data type of String. This property is intended to contain a more thorough text description of an Identified object.

#### The annotations property

The annotations property is OPTIONAL and MAY specify a set of Annotation objects that are contained by the Identified object. The Annotation class is described in more detail in Section Section 7.11.1.

#### Serialization

No complete serialization is defined for Identified, since this class is only used indirectly through its child classes. Any such child class, however, has the following form for serializing properties inherited from Identified, where CLASS\_NAME is replaced by the name of the class:

Section 7.5 TopLevel

Note that several of the properties are not in the **sbol** namespace, but are mapped to standardized terms defined elsewhere:

- identity is serialized as rdf:about
- wasDerivedFrom is serialized as prov:wasDerivedFrom
- name is serialized as dcterms:title
- description is serialized as dcterms:description

#### 7.5 TopLevel

TopLevel is an abstract class that is extended by any Identified class that can be found at the top level of an SBOL document or file. In other words, TopLevel objects are not nested inside any other object via a composite aggregation or black diamond arrow association property. Instead of nesting, composite TopLevel objects refer to subordinate TopLevel objects by their URIs using shared aggregation or white diamond arrow association properties. The TopLevel classes defined in this specification are Sequence, ComponentDefinition, Model, ModuleDefinition, Collection, and GenericTopLevel (Figure 5).

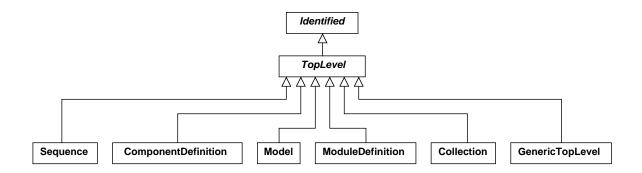

Figure 5: Classes that inherit from the TopLevel abstract class.

#### Serialization

No serialization is defined for TopLevel, since this class has no properties of its own and is only used indirectly through its child classes. All TopLevel classes are serialized one level beneath the RDF document root.

#### 7.6 Sequence

The purpose of the Sequence class is to represent the primary structure of a ComponentDefinition object and the manner in which it is encoded. This representation is accomplished by means of the elements property and encoding property (Figure 6).

#### The elements property

The elements property is a REQUIRED String of characters that represents the constituents of a biological or chemical molecule. For example, these characters could represent the nucleotide bases of a molecule of DNA, the amino acid residues of a protein, or the atoms and chemical bonds of a small molecule.

Section 7.6 Sequence

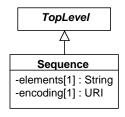

Figure 6: Diagram of the Sequence class and its associated properties.

#### The encoding property

The encoding property is REQUIRED and has a data type of URI. This property MUST indicate how the elements property of a Sequence MUST be formed and interpreted.

For example, the elements property of a Sequence with an IUPAC DNA encoding property MUST contain characters that represent nucleotide bases, such as a, t, c, and g. The elements property of a Sequence with a Simplified Molecular-Input Line-Entry System (SMILES) encoding, on the other hand, MUST contain characters that represent atoms and chemical bonds, such as C, N, O, and =.

Table 1 provides a list of possible URI values for the encoding property. The terms in Table 1 are organized by the type of ComponentDefinition (see Table 2) that typically refer to a Sequence with such an encoding. When the encoding of a Sequence is well described by one of the URIs in Table 1, it MUST contain that URI.

Encoding	URI	ComponentDefinition Type
IUPAC DNA, RNA	http://www.chem.qmul.ac.uk/iubmb/misc/naseq.html	DNA, RNA
IUPAC Protein	http://www.chem.qmul.ac.uk/iupac/AminoAcid/	Protein
SMILES	http://www.opensmiles.org/opensmiles.html	SmallMolecule

**Table 1:** URIs for specifying the encoding property of a Sequence, organized by the type of ComponentDefinition (see Table 2) that typically refer to a Sequence with such an encoding.

#### Serialization

The serialization of a Sequence MUST have the following form:

```
<sbol:Sequence rdf:about="...">
... properties inherited from identified ...
one <sbol:elements>...</sbol:elements> element
one <sbol:encoding rdf:resource="..."/> element
</sbol:Sequence>
```

The example below shows the serialization of the Sequence for a promoter. The nucleotide bases of the Sequence are serialized as the String value of its elements property, while its IUPAC DNA encoding is serialized as the URI value of its encoding property.

Section 7 SBOL Data Model

33

Section 7.7 ComponentDefinition

```
<sbol:encoding rdf:resource="http://www.chem.qmul.ac.uk/iubmb/misc/naseq.html"/>
</sbol:Sequence>
</rdf:RDF>
```

#### 7.7 ComponentDefinition

The ComponentDefinition class represents the structural entities of a biological design. The primary usage of this class is to represent structural entities with designed sequences, such as DNA, RNA, and proteins, but it can also be used to represent any other entity that is part of a design, such as small molecules, molecular complexes, and light.

As shown in Figure 7, the ComponentDefinition class describes a structural design entity using the following properties: types, roles, and sequences. In addition, this class has properties for describing and organizing the substructure of said design entity, including components, sequenceAnnotations, and sequenceConstraints.

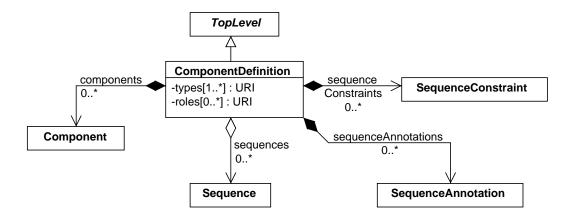

Figure 7: Diagram of the ComponentDefinition class and its associated properties.

#### The types property

The types property is a REQUIRED set of URIs that specifies the category of biochemical or physical entity (for example DNA, protein, or small molecule) that a ComponentDefinition object abstracts for the purpose of engineering design.

The types property of every ComponentDefinition MUST contain one or more URIs that MUST identify terms from appropriate ontologies, such as the BioPAX ontology or the ontology of Chemical Entities of Biological Interest (ChEBI). Table 2 provides a list of possible ontology terms for the types property and their URIs. In order to maximize the compatibility of designs, any ComponentDefinition that can be well-described by one of the terms in Table 2 MUST use the URI for that term as one of its types. Finally, if the types property contains multiple URIs, then they MUST identify non-conflicting terms (otherwise, it might not be clear how to interpret them). For example, the BioPAX terms provided by Table 2 would conflict because they specify classes of biochemical entities with different molecular structures.

#### The roles property

The roles property is an OPTIONAL set of URIs that clarifies the potential function of the entity represented by a ComponentDefinition in a biochemical or physical context.

The roles property of a ComponentDefinition MAY contain one or more URIs that MUST identify terms from ontologies that are consistent with the types property of the ComponentDefinition. For example, the roles property

Section 7 SBOL Data Model

27 28 29

Section 7.7 ComponentDefinition

ComponentDefinition Type	URI for BioPAX Term
DNA	http://www.biopax.org/release/biopax-level3.owl#DnaRegion
RNA	http://www.biopax.org/release/biopax-level3.owl#RnaRegion
Protein	http://www.biopax.org/release/biopax-level3.owl#Protein
Small Molecule	http://www.biopax.org/release/biopax-level3.owl#SmallMolecule
Complex	http://www.biopax.org/release/biopax-level3.owl#Complex

**Table 2:** BioPAX terms to specify the types property of a ComponentDefinition.

of a DNA or RNA ComponentDefinition could contain URIs identifying terms from the Sequence Ontology (SO). Table 3 contains a list of possible ontology terms for the roles property and their URIs. These terms are organized by the type of ComponentDefinition to which they SHOULD apply (see Table 2). Any ComponentDefinition that can be well-described by one of the terms in Table 3 MUST use the URI for that term as one of its roles.

ComponentDefinition Role	URI for Ontology Term	ComponentDefinition Type
Promoter	http://identifiers.org/so/SO:0000167	DNA
RBS	http://identifiers.org/so/S0:0000139	DNA
CDS	http://identifiers.org/so/SO:0000316	DNA
Terminator	http://identifiers.org/so/SO:0000141	DNA
Gene	http://identifiers.org/so/SO:0000704	DNA
Operator	http://identifiers.org/so/SO:0000057	DNA
Engineered Gene	http://identifiers.org/so/SO:0000280	DNA
mRNA	http://identifiers.org/so/S0:0000234	RNA
Effector	http://identifiers.org/chebi/CHEBI:35224	Small Molecule

Table 3: Ontology terms to specify the roles property of a ComponentDefinition, organized by the type of ComponentDefinition to which they are intended to apply (see Table 2).

#### The sequences property

The sequences property is OPTIONAL and MAY include a set of URIs that refer to Sequence objects. These objects define the primary structure of the ComponentDefinition.

Many Component Definition objects will refer to precisely one Sequence object. For certain use cases, however, it can be appropriate to refer to multiple Sequence objects. For example, a user might wish to provide two different representations of the structure of a DNA ComponentDefinition, one that represents its structure at the level of nucleotide bases and one that represents its structure at the level of atoms and bonds.

If a ComponentDefinition refers to more than one Sequence object, then these objects MUST be consistent with each other, such that well-defined mappings exist between their elements properties in accordance with their encoding properties. Furthermore, these objects MUST NOT have conflicting encoding properties. For example, the IUPAC encoding properties provided by Table 1 conflict with each other because they do not specify how to encode the same class of biochemical entity. The SMILES encoding, however, does not conflict with them because it specifies how to encode biochemical entities in general, which includes DNA, RNA, and proteins. If a ComponentDefinition refers to more than one Sequence with the same encoding, then the elements of these Sequence objects SHOULD have equal lengths. These requirements and best practices are intended to make it easier for software tools to locate any regions specified by the SequenceAnnotation objects of a ComponentDefinition on its associated Sequence objects, as well as validate whether its Sequence objects are consistent with those associated with any ComponentDefinition objects that it composes via its Component objects.

Finally, if a ComponentDefinition refers to one or more Sequence objects and its types property refers to a term from Table 2, then one of these Sequence objects MUST have the encoding that is cross-listed with this term in

44

Table 1. Conversely, if a ComponentDefinition refers to a Sequence with an encoding from Table 1, then its types property MUST refer to the term from Table 2 that is cross-listed with this encoding in Table 1. For example, if the types property of a ComponentDefinition refers to the BioPAX term for DNA, then one of the Sequence objects to which it refers (if any) MUST have an IUPAC DNA encoding, and if a ComponentDefinition refers to a Sequence with an IUPAC DNA encoding, then its types property MUST refer to the BioPAX term for DNA. These requirements are meant to provide for some degree of consistency between the types property of a ComponentDefinition and the encoding properties of the Sequence objects to which the ComponentDefinition refers.

#### The components property

The components property is OPTIONAL and MAY specify a set of Component objects that are contained by the ComponentDefinition. The set of relations between Component and ComponentDefinition objects is strictly acyclic (see Section 7.7.1).

While the ComponentDefinition class is analogous to a blueprint or specification sheet for a biological part, the Component class represents the specific occurrence of a part within a design. Hence, this class allows a biological design to include multiple instances of a particular part (defined by reference to the same ComponentDefinition). For example, the ComponentDefinition of a polycistronic gene could contain two Component objects that refer to the same ComponentDefinition of a CDS.

The components properties of ComponentDefinition objects can be used to construct a hierarchy of Component and ComponentDefinition objects. If a ComponentDefinition in such a hierarchy refers to one or more Sequence objects, and there exist ComponentDefinition objects lower in the hierarchy that refer to Sequence objects with the same encoding, then the elements properties of these Sequence objects SHOULD be consistent with each other, such that well-defined mappings exist from the "lower level" elements to the "higher level" elements in accordance with their shared encoding properties. This mapping is also subject to any restrictions on the positions of the Component objects in the hierarchy that are imposed by the SequenceAnnotation or SequenceConstraint objects contained by the ComponentDefinition objects in the hierarchy.

A DNA ComponentDefinition, for example, could refer to a Sequence with an IUPAC DNA encoding and an elements String of "gattaca." In turn, this ComponentDefinition could contain a Component that refers to a "lower level" ComponentDefinition that also refers to a Sequence with an IUPAC DNA encoding. Consequently, a consistent elements String of this "lower level" Sequence could be "gatta," or perhaps "tgta" if the Component is positioned by a SequenceAnnotation that contains a Location with an orientation of "reverse complement" (see Section 7.7.5).

#### The sequenceAnnotations property

The sequenceAnnotations property is OPTIONAL and MAY contain a set of SequenceAnnotation objects. Each SequenceAnnotation specifies and describes a potentially discontiguous region on the Sequence objects referred to by the ComponentDefinition.

In addition, each SequenceAnnotation can position a Component of the ComponentDefinition at the region specified by its Location objects (see Section 7.7.5). The sequenceAnnotations property MUST NOT contain two or more SequenceAnnotation objects that refer to the same Component in this way.

Finally, as a best practice, if a ComponentDefinition refers to a Sequence with an IUPAC encoding from Table 1, then each of its SequenceAnnotation objects that contains a Range or Cut SHOULD specify a region on the elements of this Sequence. For example, the ComponentDefinition of a eukaryotic gene could refer to a Sequence with an IUPAC DNA encoding. In order to specify the discontiguous region occupied by its CDS, this gene ComponentDefinition would need a SequenceAnnotation that contains one or more Range objects, each one specifying start and end positions that correspond to indices of the elements of its DNA Sequence.

#### The sequenceConstraints property

The sequenceConstraints property is OPTIONAL and MAY contain a set of SequenceConstraint objects. These objects describe any restrictions on the relative, sequence-based positions and/or orientations of the Component objects contained by the ComponentDefinition. For example, the ComponentDefinition of a gene might specify that the position of its promoter Component precedes that of its CDS Component. This is particularly useful when a ComponentDefinition lacks a Sequence and therefore cannot specify the precise, sequence-based positions of its Component objects using SequenceAnnotation objects.

#### Serialization

The serialization of a ComponentDefinition MUST have the form below. The components, sequenceConstraints, sequenceAnnotations, and sequences properties of a ComponentDefinition contain or reference objects belonging to the appropriate SBOL classes as their values, while the types and roles properties contain URIs that identify ontology terms as their values. As shown below, each of these objects and URIs is serialized as part of an implicit set of SBOL properties with singular rather then plural names. In particular, each object is serialized as a RDF/XML node nested within a property, while each URI (except the identity) is serialized as a rdf:resource on a property.

The example below shows the serialization for the ComponentDefinition of a promoter. The BioPAX term DnaRegion and the ChEBI term CHEBI:4705 (double-stranded DNA) are used to indicate that the type of biological entity represented by this ComponentDefinition is DNA. Its role is specified using the SO terms SO:0000167 (promoter) and the more specific SO:0000613 (bacterial\_RNApol\_promoter).

```

 </sbol:ComponentDefinition>
</rdf:RDF>
```

#### 7.7.1 ComponentInstance

The ComponentInstance abstract class is inherited by SBOL classes that represent the usage or occurrence of a ComponentDefinition within a larger design (that is, another ComponentDefinition or ModuleDefinition).

Section 7 SBOL Data Model

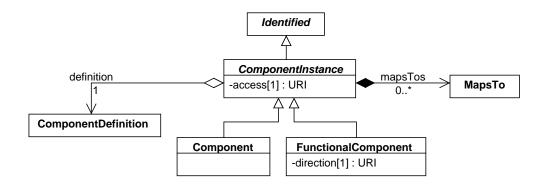

Figure 8: Diagram of the ComponentInstance class and its associated properties.

Currently, there are two subclasses of ComponentInstance:

- The Component class is used to specify the structural usage of a ComponentDefinition inside another ComponentDefinition via the components property.
- The FunctionalComponent class is used to specify the functional usage of a ComponentDefinition inside a ModuleDefinition via the functionalComponents property. This class is described in Section 7.9.2.

#### The definition property

The definition property is a REQUIRED URI that refers to the ComponentDefinition of the ComponentInstance. As described in the previous section, this ComponentDefinition effectively provides information about the types and roles of the ComponentInstance.

The definition property MUST NOT refer to the same ComponentDefinition as the one that contains the ComponentInstance. Furthermore, ComponentInstance objects MUST NOT form a cyclical chain of references via their definition properties and the ComponentDefinition objects that contain them. For example, consider the ComponentInstance objects A and B and the ComponentDefinition objects X and Y. The reference chain "X contains A, A is defined by Y, Y contains B, and B is defined by X" is cyclical.

#### The mapsTos property

The mapsTos property is OPTIONAL and MAY contain a set of MapsTo objects that refer to and link together ComponentInstance objects (both Component objects and Functional Component objects) within a larger design.

Section 7.7.3 contains a more detailed description of the MapsTo class.

#### The access property

The access property is a REQUIRED URI that indicates whether the ComponentInstance can be referred to remotely by a MapsTo on another ComponentInstance or Module contained by a different parent ComponentDefinition or ModuleDefinition (one that does not contain this ComponentInstance).

Table 4 provides a list of REQUIRED access URIs. The value of the access property MUST be one of these URIs.

In some cases, a designer might want to set the access property of a ComponentInstance such that others cannot map to the ComponentInstance when they reuse its parent ComponentDefinition. For example, a designer who is concerned about retroactivity might set the access of the ComponentInstance to "private" in order to prevent its mapping to another ComponentInstance that participates in a new Interaction as part of a composite design.

Access URI	Description
http://sbols.org/v2#public	The ComponentInstance MAY be referred to by remote MapsTo objects.
http://sbols.org/v2#private	The ComponentInstance MUST NOT be referred to by remote MapsTo objects.

Table 4: REQUIRED URIs for the access property.

#### Serialization

No serialization is defined for the ComponentInstance class, since this class is only used indirectly through the Component and FunctionalComponent subclasses.

#### 7.7.2 Component

The Component class is used to compose ComponentDefinition objects into a structural hierarchy. For example, the ComponentDefinition of a gene could contain four Component objects: a promoter, RBS, CDS, and terminator. In turn, the ComponentDefinition of the promoter Component could contain Component objects defined as various operator sites.

#### Serialization

The serialization of a Component MUST have the following form:

The example below shows the serialization of a Component that represents an instance of a promoter:

# 7.7.3 MapsTo

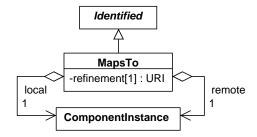

Figure 9: Diagram of the MapsTo class and its associated properties.

When ComponentDefinition and ModuleDefinition objects are composed into structural and functional hierar-

Section 7 SBOL Data Model Page 26 of 89

chies using ComponentInstance and Module objects, it is often the case that some ComponentInstance objects are intended to represent the same entity in the overall design. The purpose of the MapsTo class is to make these identity relationships clear and explicit. For example, consider a ModuleDefinition for a genetic inverter that includes a FunctionalComponent for an abstract repressor protein. When this ModuleDefinition is instantiated within a "higher level" ModuleDefinition that includes a FunctionalComponent for a LacI protein, the MapsTo object can be used to indicate that the repressor protein in the first ModuleDefinition is LacI in the context of the composite design.

In particular, a MapsTo object provides two pieces of information:

- An identity relationship between two ComponentInstance objects, the first contained by the "lower level" definition of the ComponentInstance or Module that owns the MapsTo, and the second contained by the "higher level" definition that contains the ComponentInstance or Module that owns the MapsTo. The remote property of a MapsTo refers to the first "lower level" ComponentInstance, while the local property refers to the second "higher level" ComponentInstance.
- Instructions on how to interpret local and remote ComponentInstance objects that refer to different ComponentDefinition objects (that is, non-identical objects). These are specified using the refinement property of the MapsTo class.

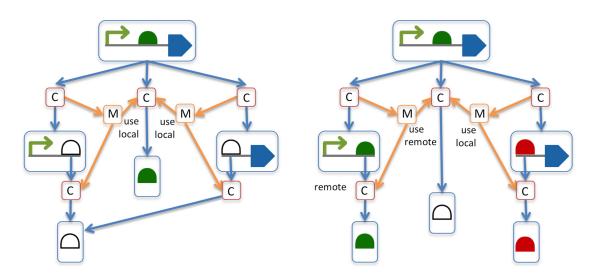

Figure 10: Linking Component objects using MapsTo entities. Boxes with diagrams represent ComponentDefinition objects, boxes with the C label represent Component objects, and boxes with the M label represent MapsTo objects. In both diagrams, a promoter-RBS ComponentDefinition and a RBS-CDS ComponentDefinition are being composed to form the ComponentDefinition of a complete transcriptional unit. In the left-hand diagram, the two Component objects inside the promoter-RBS ComponentDefinition and RBS-CDS ComponentDefinition objects both refer to an abstract RBS ComponentDefinition that lacks a sequence (white semicircle). Through the use of MapsTo objects with refinement set to useLocal, these "lower level" ComponentDefinition objects are effectively overridden by that of the green RBS in the ComponentDefinition of the complete transcriptional unit. In the right-hand diagram, however, the two "lower level" RBS ComponentDefinition objects do not lack sequences and it is the "higher level" RBS ComponentDefinition overriding that of the abstract RBS in the "higher level" ComponentDefinition.

To illustrate this concept, two examples are provided in Figure 10, in which the ComponentDefinition of a transcriptional unit is specified by composing two "lower level" ComponentDefinition objects. In both examples, the two "lower level" ComponentDefinition objects each contain a RBS Component that is intended to represent the same design entity in the "higher level" ComponentDefinition of the transcriptional unit.

In order to explicitly represent the identity relationships in this example, a new RBS Component needs to be created inside the "higher level" ComponentDefinition. This "higher level" Component then needs to be linked to the equivalent "lower level" Component objects by means of the MapsTo class, using one MapsTo object per link. For example, in order to link the "higher level" RBS Component to the "lower level" RBS Component of the promoter-RBS ComponentDefinition, a MapsTo has to be created on the "higher level" promoter-RBS Component. The local property of this MapsTo then has to refer to the "higher level" RBS Component, while its remote property has to refer to the "lower level" RBS Component. In this way, many "lower level" Component objects can be linked together at the "higher level" using as an equal number of MapsTo objects, each one referring to a different remote Component, but all referring to the same local Component.

The same types of identity relationships can also be declared between FunctionalComponent objects contained by ModuleDefinition objects, or between Component objects and FunctionalComponent objects contained by ComponentDefinition objects and ModuleDefinition objects, respectively. See Section 9 and Section B for additional examples using the MapsTo class.

#### The local property

This REQUIRED property has a data type of URI and is used to refer to the ComponentInstance contained by the "higher level" ComponentDefinition or ModuleDefinition. This local ComponentInstance MUST be contained by the ComponentDefinition or ModuleDefinition that contains the ComponentInstance or Module that owns the MapsTo.

#### The remote property

This REQUIRED property has a data type of URI and is used to refer to the ComponentInstance contained by the "lower level" ComponentDefinition or ModuleDefinition. This remote ComponentInstance MUST be contained by the ComponentDefinition or ModuleDefinition that is the definition of the ComponentInstance or Module that owns the MapsTo. Lastly, the access property of the remote ComponentInstance MUST be set to "public."

#### The refinement property

The refinement property is REQUIRED and has a data type of URI. Each MapsTo object MUST specify the relationship between its local and remote ComponentInstance objects using one of the REQUIRED refinement URIs provided in Table 5.

Refinement URI	Description
http://sbols.org/v2#useRemote	All references to the local ComponentInstance MUST dereference to the remote ComponentInstance instead.
http://sbols.org/v2#useLocal	In the context of the ComponentDefinition or ModuleDefinition that contains
	the owner of the MapsTo, all references to the remote ComponentInstance MUST
	dereference to the local ComponentInstance instead.
http://sbols.org/v2#verifyIdentical	The definition properties of the local and remote ComponentInstance ob-
	jects MUST refer to the same ComponentDefinition.
http://sbols.org/v2#merge	In the context of the ComponentDefinition or ModuleDefinition that contains
	the owner of the MapsTo, all references to the local ComponentInstance or the remote ComponentInstance MUST dereference to both objects.

Table 5: REQUIRED URIs for the refinement property.

#### Serialization

The serialization of MapsTo MUST have the following form.

	_
	4
<sbol:mapsto rdf:about=""></sbol:mapsto>	1
	41

Section 7 SBOL Data Model

Page 28 of 89

```
... properties inherited from identified ...
one <sbol:refinement rdf:resource="..."/> element
one <sbol:remote rdf:resource="..."/> element
one <sbol:local rdf:resource="..."/> element
</sbol:MapsTo>
```

In the example below, a FunctionalComponent in a "higher level" ModuleDefinition of a genetic toggle switch is linked to a FunctionalComponent in a "lower level" LacI inverter ModuleDefinition. The full example can be found in Section B.2.2.

#### 7.7.4 SequenceAnnotation

The SequenceAnnotation class describes one or more regions of interest on the Sequence objects referred to by its parent ComponentDefinition. In addition, SequenceAnnotation objects can describe the substructure of their parent ComponentDefinition through association with the Component objects contained by this ComponentDefinition.

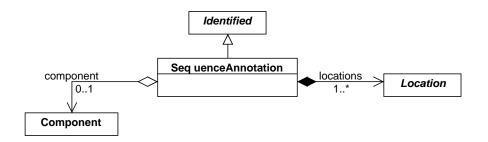

Figure 11: Diagram of the SequenceAnnotation class and its associated properties.

#### The locations property

The locations property is a REQUIRED set of one or more Location objects that indicate which elements of a Sequence are described by the SequenceAnnotation.

Allowing multiple Location objects on a single SequenceAnnotation is intended to enable representation of discontinuous regions (for example, a Component encoded across a set of exons with interspersed introns). As such, the Location objects of a single SequenceAnnotation SHOULD NOT specify overlapping regions, since it is not clear what this would mean. There is no such concern with different SequenceAnnotation objects, however, which can freely overlap in Location (for example, specifying overlapping linkers for sequence assembly).

#### The component property

The component property is OPTIONAL and has a data type of URI. This URI MUST refer to a Component that is contained by the same parent ComponentDefinition that contains the SequenceAnnotation. In this way, the properties of the SequenceAnnotation, such as its description and locations, are associated with part of the substructure of its parent ComponentDefinition.

Section 7.7 ComponentDefinition

Serialization

The serialization of a SequenceAnnotation MUST have the form below. In this template, A\_LOCATION\_SUBCLASS represents one of the Location subclasses.

```
<sbol:SequenceAnnotation rdf:about="...">
 ... properties inherited from identified
 zero or one <sbol:component rdf:resource="..."/> element
 one or more <sbol:location>
                <sbol:A_LOCATION_SUBCLASS rdf:about="...">...</sbol:A_LOCATION_SUBCLASS>
             </sbol:location> elements
</sbol:SequenceAnnotation>
```

The example below shows the serialization of a SequenceAnnotation object. It specifies the region occupied by a Component named BBa\_F2620.

```
<sbol:SequenceAnnotation rdf:about="http://partsregistry.org/cd/BBa_F2620/anno2">
 <sbol:persistentIdentity rdf:resource="http://partsregistry.org/cd/BBa_F2620/anno2"/>
 <sbol:displayId>anno2</sbol:displayId>
 <sbol:location>
   <sbol:Range rdf:about="http://partsregistry.org/cd/BBa_F2620/anno2/range">
     <sbol:persistentIdentity rdf:resource="http://partsregistry.org/cd/BBa_F2620/anno2/range"/>
     <sbol:displayId>range</sbol:displayId>
     <sbol:start>56</sbol:start>
      <sbol:end>68</sbol:end>
     <sbol:orientation rdf:resource="http://sbols.org/v2#inline"/>
   </sbol:Range>
 </sbol:location>
 <sbol:component rdf:resource="http://partsregistry.org/cd/BBa_F2620/rbs"/>
</sbol:SequenceAnnotation>
```

#### 7.7.5 Location

The Location class is extended by the Range, Cut, and GenericLocation classes.

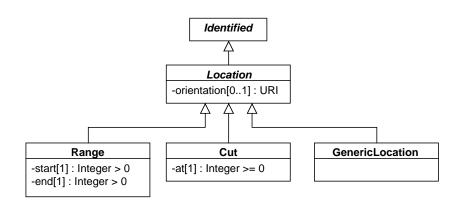

Figure 12: Diagram of the Location class and its associated properties.

#### The orientation property

The orientation property is OPTIONAL and has a data type of URI. All subclasses of Location share this property, which can be used to indicate how the region specified by the SequenceAnnotation and any associated doublestranded Component is oriented on the elements of a Sequence from their parent ComponentDefinition. Table 6

Page 30 of 89 Section 7 SBOL Data Model

provides a list of REQUIRED orientation URIs. If a Location object has an orientation, then it MUST come from Table 6.

Orientation URI	Description
http://sbols.org/v2#inline http://sbols.org/v2#reverseComplement	The region specified by this Location is on the elements of a Sequence.  The region specified by this Location is on the reverse-complement translation of the elements of a Sequence. The exact nature of this translation depends on the encoding of the Sequence.

**Table 6:** REQUIRED URIs for the orientation property

#### Range

A Range object specifies a region via discrete, inclusive start and end positions that correspond to indices for characters in the elements String of a Sequence.

Note that the index of the first location is 1, as is typical practice in biology, rather than 0, as is typical practice in computer science.

#### The start property

The start property specifies the inclusive starting position of the Range. This property is REQUIRED and MUST contain an Integer value greater than zero.

#### The end property

The end property specifies the inclusive ending position of the Range. This property is REQUIRED and MUST contain an Integer value greater than zero. In addition, this Integer value MUST be greater than or equal to that of the start property.

#### Serialization

The serialization of a Range MUST have the following form:

The example below shows the serialization of a Range object. It specifies the region between the inclusive positions 56 and 68, with an orientation of "inline."

#### Cut

The Cut class has been introduced to enable the specification of a region between two discrete positions. This specification is accomplished using the at property, which specifies a discrete position that that corresponds to the index of a character in the elements String of a Sequence (except in the case when at is equal to zero—see below).

Section 7 SBOL Data Model

#### The at property

The at property is REQUIRED and MUST contain an Integer value greater than or equal to zero. The region specified by the Cut is between the position specified by this property and the position that immediately follows it. When the at property is equal to zero, the specified region is immediately before the first discrete position or character in the elements String of a Sequence.

#### Serialization

The serialization of a Cut MUST have the following form:

The example below shows the serialization of a Cut object. It specifies a region in between positions 10 and 11, with an orientation of "inline."

```
<sbol:Cut rdf:about="http://partsregistry.org/cd/BBa_J23119/cutat10/cut">
    <sbol:persistentIdentity rdf:resource="http://partsregistry.org/cd/BBa_J23119/cutat10/cut"/>
    <sbol:displayId>cut</sbol:displayId>
    <sbol:at>10</sbol:at>
    <sbol:orientation rdf:resource="http://sbols.org/v2#inline"/>
</sbol:Cut>
```

#### GenericLocation

While the Range and Cut classes are best suited to specifying regions on Sequence objects with IUPAC encodings, the GenericLocation class is included as a starting point for specifying regions on Sequence objects with different encoding properties and potentially nonlinear structure. This class can also be used to set the orientation of a SequenceAnnotation and any associated Component when their parent ComponentDefinition is a partial design that lacks a Sequence.

#### Serialization

The serialization of a GenericLocation MUST have the following form:

```
<sbol:GenericLocation rdf:about="...">
    ... properties inherited from identified ...
    zero or one <sbol:orientation rdf:resource="..."/> element
</sbol:GenericLocation>
```

The example below shows the serialization of a GenericLocation object with an orientation of "reverse complement":

#### 7.7.6 SequenceConstraint

The SequenceConstraint class can be used to assert restrictions on the relative, sequence-based positions of pairs of Component objects contained by the same parent ComponentDefinition. The primary purpose of this class is to enable the specification of partially designed ComponentDefinition objects, for which the precise positions or orientations of their contained Component objects are not yet fully determined. Each SequenceConstraint includes the restriction, subject, and object properties.

Section 7 SBOL Data Model

Figure 13: Diagram of the SequenceConstraint class and its associated properties.

#### The subject property

The subject property is REQUIRED and MUST contain a URI that refers to a Component contained by the same parent ComponentDefinition that contains the SequenceConstraint.

#### The object property

The object property is REQUIRED and MUST contain a URI that refers to a Component contained by the same parent ComponentDefinition that contains the SequenceConstraint. This Component MUST NOT be the same Component that the SequenceConstraint refers to via its subject property.

#### The restriction property

The restriction property is REQUIRED and has a data type of URI. This property MUST indicate the type of structural restriction on the relative, sequence-based positions or orientations of the subject and object Component objects. The URI value of this property SHOULD come from the RECOMMENDED URIs in Table 7.

Restriction URI	Description
http://sbols.org/v2#precedes	The position of the subject Component MUST precede that of the object
	Component. If each one is associated with a SequenceAnnotation, then the
	SequenceAnnotation associated with the subject Component MUST specify a
	region that starts before the region specified by the SequenceAnnotation associ-
	ated with the object Component.
http://sbols.org/v2#sameOrientationAs	The subject and object Component objects MUST have the same orientation. If
	each one is associated with a SequenceAnnotation, then the orientation URIs
	of the Location objects of the first SequenceAnnotation MUST be among those
	of the second SequenceAnnotation, and vice versa.
http://sbols.org/v2#oppositeOrientationAs	The subject and object Component objects MUST have opposite orientations. If
	each one is associated with a SequenceAnnotation, then the orientation URIs
	of the Location objects of one SequenceAnnotation MUST NOT be among those
	of the other SequenceAnnotation.

Table 7: RECOMMENDED URIs for the restriction property.

#### Serialization

The serialization of a SequenceConstraint MUST have the following form:

```
<sbol:SequenceConstraint rdf:about="...">
 ... properties inherited from identified ...
 one <sbol:restriction rdf:resource="..."/> element
```

Section 7 SBOL Data Model

Page 33 of 89

20

Section 7.8 Model

```
one <sbol:subject rdf:resource="..."/> element
one <sbol:object rdf:resource="..."/> element
</sbol:SequenceConstraint>
```

The example below shows the serialization of a SequenceConstraint belonging to the ComponentDefinition of a LacI-repressible promoter. This SequenceConstraint has a "precedes" restriction that indicates that the subject Component, which represents the core of the promoter, is positioned before the object Component, which represents the LacI operator of the promoter.

#### 7.8 Model

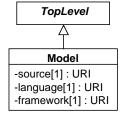

Figure 14: Diagram of the Model class and its associated properties.

The purpose of the Model class is to serve as a placeholder for an external computational model and provide additional meta-data to enable better reasoning about the contents of this model. In this way, there is minimal duplication of standardization efforts and users of SBOL can formalize the function of a ModuleDefinition in the language of their choice.

The meta-data provided by the Model class include the following properties: the source or location of the actual content of the model, the language in which the model is implemented, and the model's framework.

#### The source property

The source property is REQUIRED and MUST contain a URI reference to the source file for a model.

#### The language property

The language property is REQUIRED and MUST contain a URI that specifies the language in which the model is implemented. It is RECOMMENDED that this URI refer to a term from the EMBRACE Data and Methods (EDAM) ontology. Table 8 provides a list of terms from this ontology and their URIs. If the language property of a Model is well-described by one these terms, then it MUST contain the URI for this term as its value.

#### The framework property

The **framework** property is REQUIRED and MUST contain a URI that specifies the framework in which the model is implemented. It is RECOMMENDED this URI refer to a term from the modeling framework branch of the SBO when possible. A few suggested modeling frameworks and their corresponding URIs are shown in Table 9. If the

	http://identifiers.org/edam/format_2585

http://identifiers.org/edam/format\_3240

http://identifiers.org/edam/format\_3156

Section 7.9 ModuleDefinition

Table 8: Terms from the EDAM ontology to specify the language property of a Model.

framework property of a Model is well-described by one these terms, then it MUST contain the URI for this term as its value.

Framework	URI for SBO Term
Continuous	http://identifiers.org/biomodels.sbo/SBO:0000062
Discrete	http://identifiers.org/biomodels.sbo/SBO:0000063

Table 9: SBO terms to specify the framework property of a Model.

#### Serialization

The serialization of a Model MUST have the following form:

```
<sbol:Model rdf:about="http://www.sbolstandard.org/examples/toggleswitch">
... properties inherited from identified ...
one <sbol:source rdf:resource="..."/> element
one <sbol:language rdf:resource="..."/> element
one <sbol:framework rdf:resource="..."/> element
</sbol:Model>
```

The example below shows the serialization of a Model object that refers to a quantitative model of a genetic toggle switch. The model is implemented in the SBML language and adheres to a continuous modeling framework. Lastly, the model can be retrieved from a model repository via its source URI, which is a URL.

#### 7.9 ModuleDefinition

The ModuleDefinition class represents a grouping of structural and functional entities in a biological design. The primary usage of this class is to assert the molecular interactions and abstract function of its child entities.

As shown in Figure 15, these child entities are aggregated via the functionalComponents modules properties, while representation of their abstract function is accomplished via the roles property. More detailed descriptions of the function of a ModuleDefinition are provided by its interactions and models properties. Lastly, since ModuleDefinition objects can be more abstract and represent entities of engineering design rather than biology, they can have designated "inputs" and "outputs" expressed by the direction properties on its FunctionalComponent

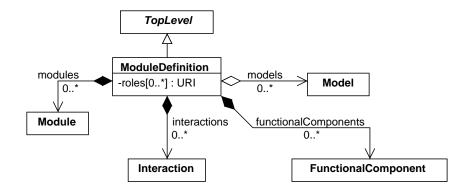

Figure 15: Diagram of the ModuleDefinition class and its associated properties.

objects.

# The roles property

The roles property is an OPTIONAL set of URIs that clarifies the intended function of a ModuleDefinition.

These URIs might identify descriptive biological roles, such as "metabolic pathway" and "signaling cascade," but they can also identify "logical" roles, such as "inverter" or "AND gate", or other abstract roles for describing the function of design. Interpretation of the meaning of such roles currently depends on the software tools that read and write them.

# The modules property

The modules property is OPTIONAL and MAY specify a set of Module objects contained by the ModuleDefinition. Note that the set of relations between Module and ModuleDefinition objects is strictly acyclic.

While the ModuleDefinition class is analogous to a specification sheet for a system of interacting biological elements, the Module class represents the occurrence of a particular subsystem within the system. Hence, this class allows a system design to include multiple instances of a subsystem, all defined by reference to the same ModuleDefinition. For example, consider the ModuleDefinition for a network of two-input repressor devices in which the particular repressors have not been chosen yet. This ModuleDefinition could contain multiple Module objects that refer to the same ModuleDefinition of an abstract two-input repressor device.

# The functionalComponents property

The functionalComponents property is OPTIONAL and MAY specify a set of FunctionalComponent objects contained by the ModuleDefinition.

Just as a Module represents an instance of a subsystem in the overall system represented by a ModuleDefinition, a FunctionalComponent represents an instance of a structural entity (represented by a ComponentDefinition) in the system. This concept allows a ModuleDefinition to assert different interactions for separate copies of the same structural entity if needed. For example, a ModuleDefinition might contain multiple FunctionalComponent objects that refer to the same promoter ComponentDefinition, but assert different interactions for these promoter copies based on their separate positions in another ComponentDefinition that represents the structure of the entire system.

# The interactions property

The interactions property is OPTIONAL and MAY specify a set of Interaction objects within the ModuleDefinition. 28

The Interaction class provides an abstract, machine-readable representation of entity behavior within a ModuleDefinition (whereas a more detailed model of the system might not be suited to machine reasoning, depending on its implementation). Each Interaction contains Participation objects that indicate the roles of the FunctionalComponent objects involved in the Interaction.

# The models property

The models property is OPTIONAL and MAY specify a set of URI references to Model objects.

Model objects are placeholders that link ModuleDefinition objects to computational models of any format. A ModuleDefinition object can link to more than one Model since each might encode system behavior in a different way or at a different level of detail.

### Serialization

The serialization of ModuleDefinition has the following form:

The example below shows a simple ModuleDefinition containing two components, a FunctionalComponent for a DNA sequence encoding constitutive expression of GFP and another for the GFP protein expressed from this sequence, plus an interaction describing that relation.

```
<sbol:ModuleDefinition rdf:about="http://sbolstandard.org/example/md/GFP_expression">
 <sbol:functionalComponent>
   <sbol:FunctionalComponent rdf:about="http://sbolstandard.org/example/md/GFP_expression/GFP_protein">
     <sbol:definition rdf:resource="http://sbolstandard.org/example/GFP"/>
      <sbol:access rdf:resource="http://sbols.org/v2#public"/>
     <sbol:direction rdf:resource="http://sbols.org/v2#output"/>
   </sbol:FunctionalComponent>
 </sbol:functionalComponent>
 <sbol:functionalComponent>
   <sbol:FunctionalComponent rdf:about="http://sbolstandard.org/example/md/GFP_expression/Constitutive_GFP">
     <sbol:definition rdf:resource="http://sbolstandard.org/example/GFP_generator"/>
     <sbol:access rdf:resource="http://sbols.org/v2#public"/>
      <sbol:direction rdf:resource="http://sbols.org/v2#none"/>
   </sbol:FunctionalComponent>
 </sbol:functionalComponent>
 <sbol:interaction>
   <sbol:Interaction rdf:about="http://sbolstandard.org/example/md/GFP_expression/express_GFP">
   </sbol:Interaction>
 </sbol:interaction>
</sbol:ModuleDefinition>
```

# 7.9.1 Module

The Module class represents the usage or occurrence of a ModuleDefinition within a larger design (that is, another ModuleDefinition).

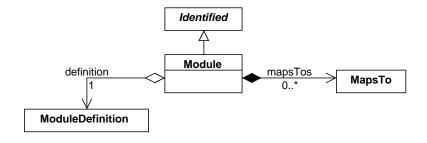

Figure 16: Diagram of the Module class and its associated properties.

### The definition property

The definition property is a REQUIRED URI that refers to the ModuleDefinition for the Module.

The definition property MUST NOT refer to the same ModuleDefinition as that which contains the Module. Furthermore, Module objects MUST NOT form a cyclical chain of references via their definition properties and the ModuleDefinition objects that contain them. For example, consider the Module objects A and B and the ModuleDefinition objects A and A. The reference chain "A" contains A, A is defined by A0" is cyclical.

### The mapsTo property

The mapsTos property is an OPTIONAL set of MapsTo objects that refer to and link ComponentInstance objects together within the heterarchy of Module, ModuleDefinition, ComponentInstance, and ComponentDefinition objects.

Section 7.7.3 contains a detailed description of the MapsTo class.

# Serialization

The serialization of Modules has the following form.

The example below specifies a TetR inverter that is being used as a part of a genetic toggle switch:

# 7.9.2 FunctionalComponent

A FunctionalComponent is an instance of a ComponentDefinition being used as part of a ModuleDefinition. The ModuleDefinition describes how the that describes how the FunctionalComponent interacts with others and summarizes their aggregate function.

The FunctionalComponent class inherits from the ComponentInstance class and therefore has the definition, access, and mapsTos properties. In addition, it has a direction property that specifies whether it serves as an

input, output, both, or neither with regards to the ModuleDefinition that contains it.

### The direction property

Each Functional Component MUST specify via the direction property whether it serves as an input, output, both, or neither for its parent ModuleDefinition object. The value for this property MUST be one of the URIs given in

Direction URI	Description
http://sbols.org/v2#in	Indicates that the FunctionalComponent is an input.
http://sbols.org/v2#out	Indicates that the FunctionalComponent is an output.
http://sbols.org/v2#inout	Indicates that the FunctionalComponent is both an input and output
http://sbols.org/v2#none	Indicates that the FunctionalComponent is neither an input or output.

translation), and other basic molecular interactions (e.g., non-covalent binding or enzymatic phosphorylation). Each Interaction includes a types property that refers to descriptive ontology terms and a participations property that describes which Functional Component objects participate in the Interaction.

Copyright Copyright

Section 7.9 ModuleDefinition

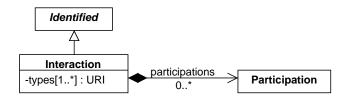

Figure 17: Diagram of the Interaction class and its associated properties.

### The types property

The types property is a REQUIRED set of URIs that describes the behavior represented by an Interaction.

The types property MUST contain one or more URIs that MUST identify terms from appropriate ontologies. It is RECOMMENDED that at least one of the URIs contained by the types property refer to a term from the occurring entity branch of the Systems Biology Ontology (SBO). (See http://www.ebi.ac.uk/sbo/main/) Table 11 provides a list of possible SBO terms for the types property and their corresponding URIs.

Interaction Type	URI for SBO Term
Inhibition	http://identifiers.org/biomodels.sbo/SBO:0000169
Stimulation	http://identifiers.org/biomodels.sbo/SBO:0000170
Genetic Production	http://identifiers.org/biomodels.sbo/SBO:0000589
Non-Covalent Binding	http://identifiers.org/biomodels.sbo/SBO:0000177

**Table 11:** SBO terms to specify the types property of an Interaction.

If an Interaction is well described by one of the terms from Table 11, then its types property MUST contain the URI that identifies this term. Lastly, if the types property of an Interaction contains multiple URIs, then they MUST identify non-conflicting terms. For example, the SBO terms "stimulation" and "inhibition" would conflict.

### The participations property

The participations property is an OPTIONAL and MAY contain a set of Participation objects, each of which identifies the roles that its referenced Functional Component plays in the Interaction.

Even though an Interaction generally contains at least one Participation, the case of zero Participation objects is allowed because it is plausible that a designer might want to specify that an Interaction will exist, even if its participants have not yet been determined.

### Serialization

The serialization of an Interaction has the following form.

The example below shows an Interaction representing an inhibition relationship (SBO:0000169) between a repressor (SBO:0000020, full Participation details shown) and a promoter:

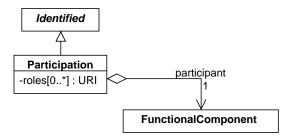

Figure 18: Diagram of the Participation class and its associated properties.

### 7.9.4 Participation

Each Participation represents how a particular Functional Component behaves in its parent Interaction.

### The roles property

The roles property is an OPTIONAL set of URIs that describes the behavior of a Participation (and by extension its referenced FunctionalComponent) in the context of its parent Interaction.

The **roles** property MAY contain one or more **URIs** that MUST identify terms from appropriate ontologies. It is RECOMMENDED that at least one of the **URIs** contained by the **types** property refer to a term from the participant role branch of the SBO. Table 12 provides a list of possible SBO terms for the **roles** property and their corresponding **URIs**.

Participation Role	URI for SBO Term
Inhibitor	http://identifiers.org/biomodels.sbo/SBO:0000020
Stimulator	http://identifiers.org/biomodels.sbo/SBO:0000459
Reactant	http://identifiers.org/biomodels.sbo/SBO:0000010
Product	http://identifiers.org/biomodels.sbo/SBO:0000011
Ligand	http://identifiers.org/biomodels.sbo/SBO:0000280
Non-Covalent Complex	http://identifiers.org/biomodels.sbo/SBO:0000253

**Table 12:** SBO terms to specify the roles property of a Participation.

If a Participation is well described by one of the terms from Table 12, then its roles property MUST contain the URI that identifies this term. Lastly, if the roles property of a Participation contains multiple URIs, then they

Section 7.10 Collection

MUST identify non-conflicting terms. For example, the SBO terms "stimulator" and "inhibitor" would conflict.

### The participant property

The participant property MUST specify precisely one FunctionalComponent object that plays the designated role in its parent Interaction object.

### Serialization

The serialization of Participation objects has the following form.

In the example below, the role of participating FunctionalComponent is defined to be inhibitor, using the SBO:0000020 term. This component is specified using the participant property of the Participation entity.

```
<sbol:Participation rdf:about="http://sbolstandard.org/example/laci_inverter/LacI_pLacI/P03023">
    <sbol:role rdf:resource="http://identifiers.org/biomodels.sbo/SB0:0000020"/>
    <sbol:participant rdf:resource="http://sbolstandard.org/example/laci_inverter/TF"/>
    </sbol:Participation>
```

# 7.10 Collection

The Collection class is a class that groups together a set of TopLevel objects that have something in common. Some examples of Collection objects:

- Results of a query to find all ComponentDefinition objects in a repository that function as promoters.
- A set of ModuleDefinition objects representing a library of genetic logic gates.
- A ModuleDefinition for a complex design, and all of the ModuleDefinition, ComponentDefinition, Sequence, and Model objects used to provide its full specification.

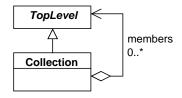

Figure 19: Diagram of the Collection class and its associated properties.

# The members property

The members property of a Collection is OPTIONAL and MAY contain a set of URI references to zero or more TopLevel objects.

Serialization

The serialization of a Collection has the following form:

```
<sbol:Collection rdf:about="...">
... properties inherited from identified ...
zero or more <sbol:member rdf:resource="..."/> element
</sbol:Collection>
```

The example below shows the serialization of a Collection object grouping together a library of constitutive promoters.

# 7.11 Annotation and Extension of SBOL

SBOL does not currently represent all types of biological design data, since many of these data types (e.g., biological context and design performance metrics) lack a clear consensus on their proper representation. In addition, some types of biological data are not directly relevant to design and are therefore outside of the scope of SBOL.

To enable representation of these data, SBOL allows developers to embed custom data within SBOL objects and documents, such that these data can be exchanged without being damaged or lost. This annotation and extension mechanism is designed to enable new types of data to be easily incorporated into the SBOL standard once there is community consensus on their proper representation.

Several methods are supported for connecting the SBOL data model with other types of application-specific data:

- Custom data can be added to an SBOL object by annotating that object with non-conflicting properties. These properties could contain literal data types such as Strings or URIs that require a resolution mechanism to obtain external data. An example is annotating a ComponentDefinition with a property that contains a String description and URI for the parts registry from which its source data was originally imported.
- Custom data in the form of independent objects can be added to an SBOL document by creating GenericTopLevel objects and annotating them as described above. An example is a GenericTopLevel object that is annotated such that it represents a data sheet that describes the performance of a ModuleDefinition in a particular context.
- Finally, just as custom objects can be embedded in an SBOL document, external documents can embed or refer to SBOL objects. Support for this last case is not explicitly provided in this specification. Rather, this case depends on the external non-SBOL system managing its relationship to SBOL and data serialized in RDF/XML, and is included here for completeness.

### 7.11.1 Annotating SBOL objects

Each Identified object MAY contain any number of Annotation objects that store data in the form of name/value property pairs. The qName is REQUIRED and MUST contain a QName, which is composed of a namespace, an

OPTIONAL prefix, and a local name. The qName property MUST be stored in the data model to allow for proper serialization as described below. The value property is also REQUIRED and MUST contain a literal (i.e., a String, Integer, Double, Boolean), URI, or NestedAnnotations object. A NestedAnnotations object MUST contain nestedQName and nestedURI properties, and it MAY contain an annotations property that contains zero or more Annotation objects.

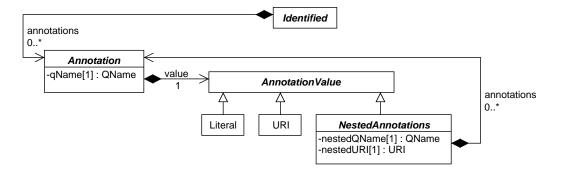

Figure 20: Diagram of the Annotation class and its association with Identified and AnnotationValue objects, which is used for annotating SBOL entities with application specific data.

### Serialization

The serialization of an Annotation has the following form:

The qName property specifies a namespace, prefix, and local part/name. The use of such qualified names is described in detail by the W3C (http://www.w3.org/TR/1999/REC-xml-names-19990114/#ns-using). Essentially, the "xmlns" property defines the prefix String to use as an alias for the namespace. The prefix can be any String. Its use is OPTIONAL, since it simply replaces the full namespace, thereby making the serialization easier for a human to read.

The first form of Annotation shown above is for an Annotation that contains a literal as its value. The second form is for an Annotation that contains a URI as its value. Finally, the third form is for an Annotation that contains a NestedAnnotations object as its value. In the last case, the nestedQName property specifies the nested namespace, nested prefix, and nested local part/name, while the nestedURI property species the URI for the

### NestedAnnotations object.

The example below shows how the serialization for a promoter ComponentDefinition can be annotated with custom data. Annotations are added containing the relevant information from the iGEM Parts Registry. Each property serialization of an Annotation is qualified with the http://www.partsregistry.org/namespace, which is prefixed using pr. The first Annotation is named pr:group. It specifies the iGEM group that has designed the promoter and has a String value. The second Annotation is named pr:experience. It contains a URI value that is serialized as an RDF resource and can be resolved to the information Web page on the Parts Registry for the promoter. Finally, the third Annotation is named pr:information. It contains a NestedAnnotations object that is serialized as shown and includes information about the regulatory details of the promoter using Annotations that correspond to Parts Registry categories.

### 7.11.2 GenericTopLevel

Custom data can also be embedded at the top level of an SBOL document. The <code>GenericTopLevel</code> class is used to represent top-level entities whose purpose is to contain a set of annotations that are independent of any other class of SBOL object. Entities that have independent existence and are not recognized by the SBOL standard are deserialized to <code>GenericTopLevel</code> objects. These <code>GenericTopLevel</code> objects can be safely used by tools to exchange non-SBOL data.

As with other TopLevel objects, GenericTopLevel objects MAY include the properties displayId, name, description, etc. The type of data annotating a GenericTopLevel object is indicated using the REQUIRED rdfType property, which MUST contain a QName. As before with the qName property, the rdfType property is used to set the namespace, prefix, and local part/name during serialization.

# Serialization

The serialization of the GenericTopLevel class has the following form, where the prefix, namespace, and local part/name are defined by the rdfType property:

```
<?xml version="1.0" ?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:sbol="http://sbols.org/v2#"
    xmlns:applicationPrefix="APPLICATION_NAMESPACE"
    ...
>
```

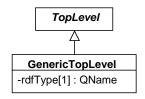

Figure 21: Diagram of the GenericTopLevel class and its associated properties, which is used for embedding externally defined entities into SBOL documents.

```
<applicationPrefix:APPLICATION_OBJECT_NAME rdf:about="...">
    ... properties inherited from identified ...
    ... any non-conflicting application-specific properties ...
</applicationPrefix:APPLICATION_OBJECT_NAME>
```

The example below shows how a datasheet object can be added to an SBOL document using the <code>GenericTopLevel</code> class. The J23119 promoter <code>ComponentDefinition</code> is annotated with the <code>myapp:datasheet</code> property that contains the <code>URI</code> of a <code>TopLevel</code> Datasheet object. The Datasheet object is further annotated with the transcription rate and <code>URI</code> for the actual characterization data using the <code>myapp:transcriptionRate</code> and <code>myapp:characterizationData</code> properties, respectively. As specified by their <code>rdfType</code> and <code>qName</code> properties, the <code>TopLevel</code> Datasheet object and all <code>Annotation</code> objects in this example are serialized with the custom <code>http://www.myapp.org/</code> namespace and <code>myapp</code> prefix.

```

# 8 Mapping Between SBOL 1.1 and SBOL 2.0

Figure 22 depicts the mapping of SBOL 1.1 classes to SBOL 2.0 classes, indicating corresponding classes/properties by color. The SBOL 2.0 Model and ModuleDefinition classes have no SBOL 1.1 equivalent, and thus are not shown. In particular:

- SBOL 1.1 Collection objects containing DnaComponent objects map to SBOL 2.0 Collection objects that contain ComponentDefinition objects with DNA types properties.
- SBOL 1.1 DnaComponent objects maps to SBOL 2.0 ComponentDefinition objects with DNA types properties.
- SBOL 1.1 DnaSequence objects maps to an SBOL 2.0 Sequence objects with IUPAC DNA encoding properties.
- SBOL 1.1 SequenceAnnotation objects with bioStart and bioEnd properties map to SBOL 2.0 SequenceAnnotation objects that contain Range objects.
- SBOL 1.1 SequenceAnnotation objects that lack bioStart and bioEnd properties map to an SBOL 2.0 SequenceAnnotation objects that contain GenericLocation objects.
- Each SBOL 1.1 SequenceAnnotation also maps to an SBOL 2.0 Component, which represents the instantiation or usage of the appropriate ComponentDefinition.
- Each SBOL 1.1 precedes property maps to an SBOL 2.0 SequenceConstraint that specifies a precedes restriction property.

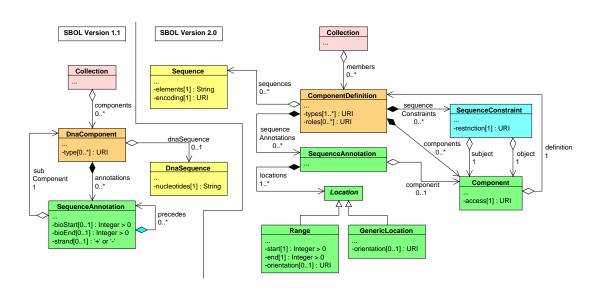

Figure 22: The mapping from the SBOL 1.1 data model to the SBOL 2.0 data model, indicating corresponding class-es/properties by color.

# 9 Data Model Examples

This section illustrates how to use the SBOL data model by specifying the design of a LacI/TetR toggle switch similar to those constructed in Gardner et al. (2000). This design is visualized conceptually in Figure 23 and in detail in Figure 24.

Conceptually, the toggle switch is constructed from two mutually repressing genes. With repressors LacI and TetR, this results in a bi-stable system that will tend to settle into a state where precisely one of the two repressors is strongly expressed, repressing the other. Each of these repressors can have its activity disrupted by a small molecule (IPTG for LacI, aTc for TetR), which enables the system to be "toggled" from one state to the other by dosing it with the appropriate small molecule.

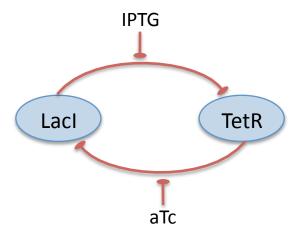

Figure 23: Conceptual diagram of Lacl/TetR toggle switch: the Lacl and TetR transcription factors are arranged to mutually repress each other's expression, creating a bi-stable system. Transition between the two states is triggered by the small-molecule signals aTc (which disrupts TetR repression) and IPTG (which disrupts Lacl repression).

The LacI/TetR toggle switch is modeled in SBOL as two parallel hierarchies of structure and function. The structural hierarchy of the toggle switch is represented using ComponentDefinitions:

- The base elements of the hierarchy are DNA components, transcription factor proteins, and small molecules. As an example, Figure 25 is a UML diagram of the ComponentDefinition objects that represent these elements.
- Base elements are composed to form more complex structures at the top of the hierarchy, including genes and non-covalent complexes between transcription factor proteins and small molecules. As an example, Figure 26 is a UML diagram of the composite ComponentDefinition objects that represent the TetR gene and IPTG-LacI complex.

The functional hierarchy of the toggle switch is represented using ModuleDefinitions:

- The base elements of the hierarchy are LacI-dependent repression of TetR expression (the LacI inverter) and TetR-dependent repression of LacI (the TetR inverter). As an example, Figure 27 is a UML diagram of the ModuleDefinition that represents the LacI inverter.
- Base elements are composed to form the toggle switch at the top of the hierarchy. As an example, Figure 28 is a UML diagram of the ModuleDefinition that represents the toggle switch.

24

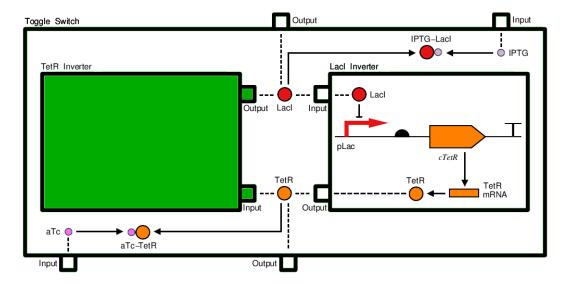

Figure 24: Design of a Lacl/TetR toggle switch. This design is composed of two inverter sub-designs, each containing a single gene. These genes mutually repress each other's expression via their encoded protein transcription factors, Lacl and TetR. Furthermore, both Lacl and TetR are bound by specific small molecules that sequester them and prevent them from acting as repressors. In this design, arrows represent different molecular interactions, including the repression of pLac via Lacl, the non-covalent binding of IPTG to Lacl, the transcription of TetR mRNA, and the translation of TetR. Dashed lines serve to map between transcription factors in the inverter sub-designs and those in the overall toggle switch design.

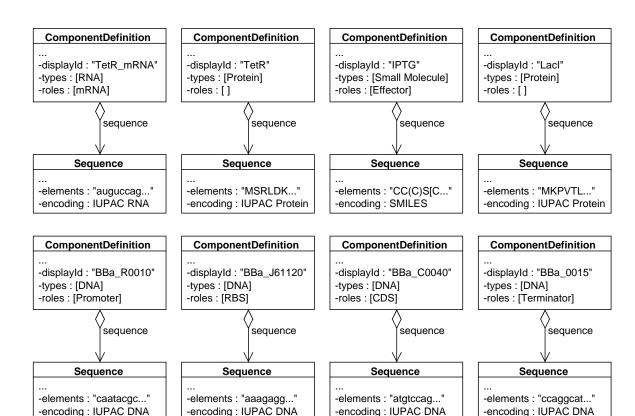

Figure 25: ComponentDefinition objects for the Lacl inverter. These include ComponentDefinition objects based on DNA parts from the iGEM Parts Registry and ComponentDefinition objects that represent TetR mRNA, TetR, Lacl, and IPTG. Each ComponentDefinition is associated with a Sequence that has an IUPAC DNA/RNA or IUPAC protein encoding, except the ComponentDefinition of IPTG, which is associated with a Sequence that has a SMILES encoding.

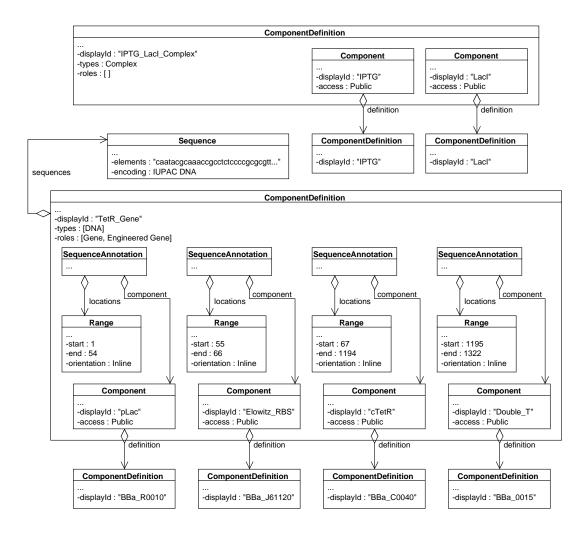

Figure 26: Composite ComponentDefinition objects for the Lacl inverter. In the case of the ComponentDefinition that represents the TetR gene, its sub-Component objects are located as Ranges along its Sequence using SequenceAnnotation objects. The ComponentDefinition that represents the IPTG-Lacl complex, however, has no Sequence and its sub-Component objects are composed without any data about their relative positions.

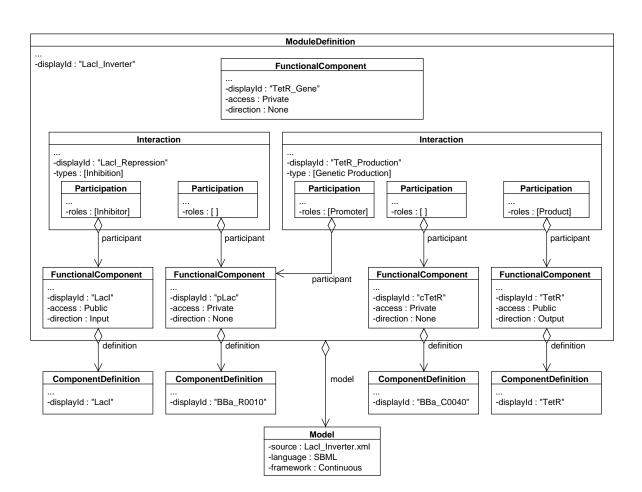

Figure 27: ModuleDefinition of the LacI inverter. This ModuleDefinition contains FunctionalComponent objects that instantiate the ComponentDefinition objects for the LacI/TetR transcription factors and TetR gene. The FunctionalComponent for the TetR gene as a whole does not participate in any Interaction and merely indicates that the function of the gene is described by the LacI inverter ModuleDefinition. The remaining FunctionalComponent objects participate in a repression Interaction and a genetic production Interaction, thereby indicating which biological structures carry out the function of the LacI inverter ModuleDefinition. In this case, the transcription and translation of TetR are represented as a single genetic production Interaction that abstracts away the presence of the intermediate TetR mRNA. In addition, this ModuleDefinition is also associated with a continuous Model written in the SBML source file "LacI\_Inverter.xml."

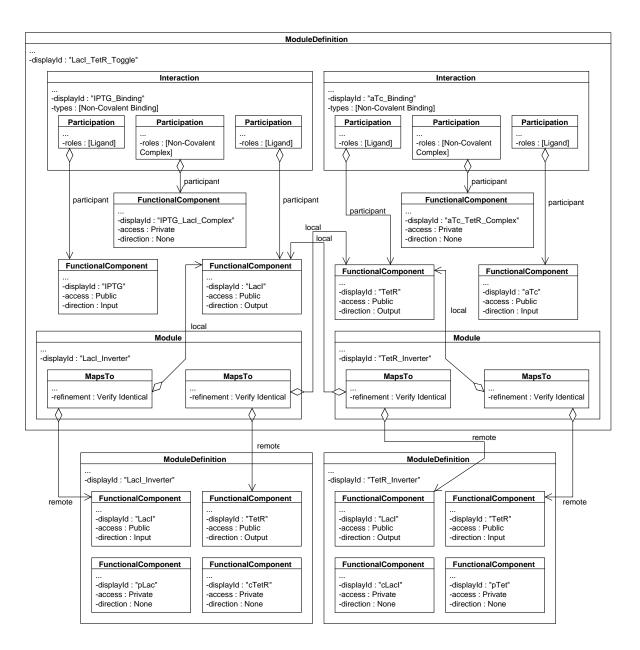

Figure 28: Composite ModuleDefinition of the Lacl/TetR toggle switch. This ModuleDefinition contains the Module objects that instantiate Lacl and TetR inverter ModuleDefinition objects. It also contains FunctionalComponent objects that instantiate the ComponentDefinition objects for the Lacl/TetR transcription factors and IPTG/aTc small molecules. These FunctionalComponent objects each participate in a non-covalent binding Interaction. To complete the composition of the toggle switch, MapsTo objects are used to indicate that the output of the Lacl inverter ModuleDefinition is identical to the input of the TetR inverter ModuleDefinition and vice versa.

# 10 SBOL RDF Serialization

In order for SBOL objects to be readily stored and exchanged, it is important that they are able to be *serialized*, i.e., converted to a sequence of bytes that can be stored in a file or exchanged over a network. The serialization format for SBOL is designed to meet several competing requirements. First, SBOL needs to support ad-hoc annotations and extensions. Second, SBOL needs to support processing by general database and semantic web software tools that have little or no knowledge of the SBOL data model. Finally, it ought to be relatively simple to write a new software implementation, so that SBOL can be readily used even in software environments where community-maintained implementations are not available.

To meet these goals, the canonical serialization of SBOL has been selected to be a strict dialect of RDF/XML Beckett and McBride (2004), a syntactic standard defined for Semantic Web data exchange. This serialization provides a standard base from which to meet further requirements. Moreover, it allows any RDF/XML-aware software tool to consume and operate on an SBOL file without needing any customization to support SBOL. Where possible, we have re-used predicates from widely-used terminologies (such as Dublin Core DCMI Usage Board (2012)) to expose as much of the data as practical to such standard RDF tooling.

Arbitrary RDF/XML, however, provides a sometimes problematically large amount of flexibility in how equivalent data can be serialized. This flexibility can result in different serializations when processing RDF/XML files using standard off-the-shelf XML tools, such as DOM-OO mappings. To address this issue, we define a canonical association between the nesting of data structures within the SBOL UML data model and the RDF/XML file. For all ownership associations (filled diamonds), the RDF/XML for the owned entity is embedded within the owner's RDF/XML (note, however, that the property values MAY be listed in any order). For all associations that are by reference (open diamonds), the RDF/XML for the referenced property is linked via a resource URI. For example, the serialization of a ComponentDefinition embeds the serializations of the SequenceConstraint and Component objects associated with it. Those SequenceConstraint objects, however, link to the Component objects with a URI rather than embedding another copy.

Every SBOL document MUST be a valid RDF/XML document. Accordingly, each SBOL document starts with an XML declaration that has its XML version set to "1.0." As shown in the example below, this declaration is then followed by an rdf:RDF XML element that includes the namespace declarations for RDF, Dublin Core, PROV, and SBOL. The SBOL namespace, which is http://sbols.org/v2#, is used to indicate which entities and properties in the SBOL document are defined by SBOL, and MUST NOT be used for any entities or properties not defined in this specification.

```
<?xml version="1.0" ?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#" xmlns:dcterms="http://purl.org/dc/terms/" xmlns:prov="http://www.
w3.org/ns/prov#" xmlns:sbol="http://sbols.org/v2#">
...
</rdf:RDF>
```

All first-class SBOL data types (i.e., those enumerated in Section 7) have an associated identifying URI. In the RDF, this is the resource URI used by instances of that type. For example, ComponentDefinition has the type URI sbol:ComponentDefinition. Properties and associations are then asserted as nested RDF/XML assertions. Section 7 provides the serialization template and an example at the end of its description of each data type. All of the data types that are TopLevel are so named because they always appear at the top-most level of the RDF/XML serialization. All other data types will always appear nested within their parent container and, ultimately, some TopLevel object. For example, a ComponentDefinition is a TopLevel and therefore listed at the top-most level of the RDF/XML serialization, and contains its SequenceConstraint objects, since they are not TopLevel. Its Sequence, however, is also TopLevel and is therefore not nested within and instead linked via a URI.

Each instance of a first-class SBOL data type MAY have annotations attached, as described in Section 7.11. These annotations are composed of a name and a value. They are serialized to RDF as a conceptual triple with the subject being the identity of the instance they annotate, the predicate being the name of the annotation, and the object

22

being the value of that annotation. Annotation values are always nested within the RDF/XML serialization of the instance that they annotate. For example, a ModuleDefinition might add a DOI annotation that links to the scientific article that first described the system that it represents.

SBOL also supports top-level, user-defined data, again as described in Section 7.11. This is to allow non-standardized but necessary information to be carried around as part of a design. For example, a particular sub-community might have an internal standard for genetic device characterization data sheets. Such data can be represented as a GenericTopLevel object with internal structured annotations. For example, each individual data sheet might be contained in its own GenericTopLevel instance. This custom data is serialized into the RDF/XML in the usual way, as an RDF/XML block at the top level of the file. Other objects can refer to this entity through their annotations by reference, and this generic top-level entity can refer to other entities via references. For example, a ModuleDefinition might use an annotation to refer to the data sheet GenericTopLevel that documents its properties.

By adopting this paradigm of RDF/XML serialization, SBOL is able to adapt to future changes in the standard without requiring large-scale alterations to the RDF files. Since exactly the same scheme is used to serialize annotations as is used to serialize specification-defined properties and associations, it is possible to update the SBOL standard to recognize a different range of properties and associations. Those properties not recognized by the specification will always be available through the API as annotations. Similarly, by allowing arbitrary top-level entities in a SBOL file, we enable future specifications or extensions to ratify the structure of other top-level objects. These entities would then become part of the explicit data model, but the identical RDF serialization would be used. Applications lacking support for a given extension can safely read in, manipulate, and write out the top-level data that is not understood, treating it as a top-level structured annotation, without data loss or corruption. Finally, the very regimented control of nesting versus referencing also allows the XML structure to be very predictable, enabling XML/DOM-based tooling to work with SBOL RDF/XML files safely.

# 11 Recommended Best Practices

# 11.1 Use of the Version Property

Once an SBOL object has been published where others might have access it (e.g., to an online repository), it might be the case that other objects come to depend on the particular contents of the published object. Thus, in order to avoid creating conflicting data, if a person wants to change the properties of a published object, they SHOULD do so by making a new copy of object that incorporates the change and has an identity property that contains a new URI.

The relationship between the old and new objects (i.e., that the new object was derived from the old object), however, is not visible unless it is explicitly declared. This is RECOMMENDED to be done using the persistentIdentity, and version properties. The preferred practice for declaring such a relationship is to use the same persistentIdentity for both objects, but give the newer object a later version. Then, when the new object is published, it can be clear to both humans and machines that this object is intended to update the previously published object. In this way, when a user wants the latest version of an object, they can obtain it by referencing the object via its persistentIdentity and rely on a tool to find the object with that persistentIdentity and the latest version.

As stated in Section 7.4, it is RECOMMENDED that version numbering follow the conventions of semantic versions (http://semver.org/), particularly as implemented by Maven (http://maven.apache.org/). This convention represents versions as sequences of numbers and qualifiers separated by the characters . and – and compared in lexicographical order (for example, 1 < 1.3.1 < 2.0-beta). For a full explanation, see the linked resources.

# 11.2 Compliant SBOL Objects

Maintaining unique identity URIs for all SBOL objects can be a very challenging implementation task. To reduce this burden, users of SBOL 2.0 are encouraged to follow a few simple rules when constructing the identity properties and related properties for SBOL objects. When these rules are followed in constructing an SBOL object, we say that this object is *compliant*. These rules are as follows:

- 1. The identity of a compliant SBOL object MUST begin with a *URI prefix* that maps to a domain over which the user has control. Namely, the user can guarantee uniqueness of identities within this domain.
- 2. The persistentIdentity and displayId properties are REQUIRED of a compliant SBOL object.
- 3. The persistentIdentity of a compliant TopLevel object MUST end with a delimiter ('/', '#', or ':') followed by the displayId of the object.
- 4. The persistentIdentity of a compliant SBOL object that is not also a TopLevel object MUST begin with the persistentIdentity of its parent object and be immediately followed by a delimiter ('/', '#', or ':') and the displayId of the compliant object.
- 5. If a compliant SBOL object is not given a version, then its identity and persistentIdentity properties MUST contain the same URI.
- 6. If a compliant SBOL object has a version, then its identity property MUST contain a URI of the form "\( persistentIdentity \) / \( \lambda version \rangle ".
- 7. The version of a compliant SBOL object that is not also a TopLevel object MUST contain the same String as the version property of the compliant object's parent object.
- 8. The identity, persistentIdentity, displayId, and version properties of a compliant SBOL object MUST NOT be changed once set.

All examples in this specification use compliant URIs.

Section 11.3 Annotations: Embedded Objects vs. External References

# 11.3 Annotations: Embedded Objects vs. External References

When annotating an SBOL document with additional information, there are two general methods that can be used:

- Embed the information in the SBOL document, either as non-SBOL properties or GenericTopLevel objects.
- Store the information separately and annotate the SBOL document with URIs that point to it.

In theory, either method can be used in any case. (Note that a third case not discussed here is to use SBOL to annotate external objects with linking to SBOL documents, rather than annotate SBOL documents with links external objects.)

In practice, embedding massive amounts of non-SBOL data into SBOL documents is likely to cause problems for people and software tools trying to manage and exchange such documents. Therefore, it is RECOMMENDED that small amounts of information (e.g., design notes or preferred graphical layout) be embedded in the SBOL model, while large amounts of information (e.g., the contents of the scientific publication from which a model was derived or flow cytometry data that characterizes performance) be linked with URIs pointing to external resources. The boundary between "small" and "large" is left deliberately vague, recognizing that it will likely depend on the particulars of a given SBOL application.

# 11.4 Completeness and Validation

RDF documents containing serialized SBOL objects might or might not be entirely self-contained. A SBOL document is self-contained or "complete" if every SBOL object referred to in the document is contained in the document. It is RECOMMENDED that serializations be complete whenever practical. In order words, when serializing an SBOL object, serialize all of the other objects that it points to, then serialize all of the other objects that these objects point to, etc., until the document is complete.

It is important to note that there is no guarantee that an RDF document contains valid SBOL. When an RDF document is describilized to SBOL objects, the program doing so SHOULD verify that all of the property values encoded therein have the right data type (e.g., that the object pointed to by the sequences property of a ComponentDefinition is really a Sequence). For complete files, this validation can be carried out entirely locally. For files that are not complete, an implementation either needs to have a means of validating those external references (e.g., by retrieving them from various repositories), or it needs to mark them as unverified and not depend on their correctness.

# 11.5 Recommended Ontologies for External Terms

External ontologies and controlled vocabularies are an integral part of SBOL. SBOL uses URIs to access existing biological information through these resources. New SBOL specific terms are defined only when necessary. For example, ComponentDefinition types, such as DNA or protein, are described using BioPAX terms. Similarly, the roles of a DNA ComponentDefinition are described via SO terms. Although RECOMMENDED ontologies have been indicated in relevant sections where possible, other resources providing similar terms can also be used. A summary of these external sources can be found in Table 13.

Section 11.5 Recommended Ontologies for External Terms

SBOL Entity	Property	Preferred External Resource	More Information
ComponentDefinition	types	BioPAX	http://www.biopax.org
	roles	SO (DNA or RNA)	http://www.sequenceontology.org
	roles	CHEBI (small molecule)	https://www.ebi.ac.uk/chebi/
Interaction	types	SBO (occurring entity branch)	http://www.ebi.ac.uk/sbo/main/
Participation	roles	SBO (participant roles branch)	http://www.ebi.ac.uk/sbo/main/
Model	language	EDAM	http://bioportal.bioontology.org/ ontologies/EDAM
	framework	SBO (modeling framework branch)	http://www.ebi.ac.uk/sbo/main/

Table 13: Preferred external resources from which to draw values for various SBOL properties.

# A Validation Rules

This section summarizes all the conditions that either MUST be or are RECOMMENDED to be true of an SBOL Version 2.0 document. There are different degrees of rule strictness. Rules of the former kind are strict SBOL validation rules—data encoded in SBOL MUST conform to all of them in order to be considered valid. Rules of the latter kind are consistency rules that SBOL data are RECOMMENDED to adhere to as a best practice. To help highlight these differences, we use the following symbols next to the rule numbers:

- ✓ A checked box indicates a strong REQUIRED condition for SBOL conformance. If a SBOL document does not follow this rule, it does not conform to the SBOL specification. (Mnemonic intention behind the choice of symbol: "This MUST be checked.")
- A triangle indicates a weak REQUIRED condition for SBOL conformance. While this rule MUST be followed, it can be difficult, if not impossible, for a machine to automatically check whether the rule has been followed. (Mnemonic intention behind the choice of symbol: "This is a cause for warning.")
- ★ A star indicates a RECOMMENDED condition for following best practices. This rule is not strictly a matter of SBOL conformance, but its recommendation comes from logical reasoning. If an SBOL document does not follow this rule, it is still valid SBOL, but it might have degraded functionality in some tools. (Mnemonic intention behind the choice of symbol: "You're a star if you heed this.")

The validation rules listed in the following subsections are all believed to be stated or implied in the rest of this specification document. They are enumerated here for convenience and to provide a "master checklist" for SBOL validation. In case of a conflict between this section and other portions of the specification (though there are believed to be none), this section is considered authoritative for the purpose of determining the validity of an SBOL document.

For convenience and brevity, we use the shorthand "sbol:x" to stand for an attribute or element name x in the namespace for the SBOL specification, using the namespace prefix sbol. In reality, the prefix string can be different from the literal "sbol" used here (and indeed, it can be any valid XML namespace prefix that the software chooses). We use "sbol:x" because it is shorter than to write a full explanation everywhere we refer to an attribute or element in the SBOL specification namespace.

### General rules for an SBOL document

**sbol-10101** ✓ An SBOL document MUST declare the use of the following XML namespace:

"http://sbols.org/v2#". Reference: Section 10 on page 54

sbol-10102 

✓ An SBOL document MUST declare the use of the following XML namespace:

"http://www.w3.org/1999/02/22-rdf-syntax-ns#".

Reference: Section 10 on page 54

 $\textbf{sbol-10103} \ \ \, \overline{\texttt{M}} \qquad \text{If an SBOL document includes any } \\ \textbf{name or description properties, then it MUST declare the} \\ \\ \textbf{1} \\ \textbf{2} \\ \textbf{3} \\ \textbf{4} \\ \textbf{4} \\ \textbf{5} \\ \textbf{5} \\ \textbf{6} \\ \textbf{6} \\ \textbf{6} \\ \textbf{6} \\ \textbf{7} \\ \textbf{6} \\ \textbf{6}$ 

use of the following XML namespace:

"http://purl.org/dc/terms/". Reference: Section 10 on page 54

of the following XML namespace: "http://www.w3.org/ns/prov#".

Reference: Section 10 on page 54

Section A Validation Bules

#### Rules for the Identified class

- The identity property of an Identified object is REQUIRED and MUST contain a URI that adheres to the syntax defined by:
  - "http://www.w3.org/1999/02/22-rdf-syntax#about"

Reference: Section 7.4 on page 16

- sbol-10202 The identity property of an Identified object MUST be globally unique. Reference: Section 7.4 on page 16
- The persistentIdentity property of an Identified object is OPTIONAL and MAY contain a **URI** that MUST adhere to the syntax defined by: "http://www.w3.org/1999/02/22-rdf-syntax#about"

Reference: Section 7.4 on page 16

The displayId property of an Identified object is OPTIONAL and MAY contain a String that MUST be composed of only alphanumeric or underscore characters and MUST NOT begin with a digit.

Reference: Section 7.4 on page 16

- The displayId property of an Identified object SHOULD be locally unique. sbol-10205 ★ Reference: Section 7.4 on page 16
- The version property of an Identified object is OPTIONAL and MAY contain a String that MUST be composed of only alphanumeric characters, underscores, hyphens, or periods and MUST begin with a digit. Reference: Section 7.4 on page 16

- The version property of an Identified object SHOULD follow the conventions of semantic sbol-10207 ★ versioning as implemented by Maven. Reference: Section 7.4 on page 16
- The wasDerivedFrom property of an Identified object is OPTIONAL and MAY contain a URI. Reference: Section 7.4 on page 16
- The wasDerivedFrom property of an Identified object MUST NOT contain a URI reference to the Identified object itself. Reference: Section 7.4 on page 16
- sbol-10210 A Identified objects MUST NOT form circular reference chains via their wasDerivedFrom properties.

Reference: Section 7.4 on page 16

- sbol-10211 A If the wasDerivedFrom property of one Identified object refers to another Identified object with the same persistentIdentity property, then version property of the second Identified object MUST precede that of the first if both objects have a version. Reference: Section 7.4 on page 16
- The name property of an Identified object is OPTIONAL and MAY contain a String. Reference: Section 7.4 on page 16
- The description property of an Identified object is OPTIONAL and MAY contain a String. Reference: Section 7.4 on page 16
- The annotations property of an Identified object is OPTIONAL and MAY contain a set of Annotation objects. Reference: Section 7.4 on page 16

40

sbol-10215 ★ The displayId property of a compliant Identified object is REQUIRED.

Reference: Section 11.2 on page 56

sbol-10216 ★ The persistentIdentity property of a compliant TopLevel object is REQUIRED and MUST contain a URI that ends with a delimiter ('/', '#', or ':') followed by the displayId of the TopLevel object.

Reference: Section 11.2 on page 56

sbol-10217 ★ The persistentIdentity property of a compliant Identified object that is not also a TopLevel object is REQUIRED and MUST contain a URI that begins with the persistentIdentity of the compliant object's parent and is immediately followed by a delimiter ('/', '#', or ':') and the displayId of the compliant object.

Reference: Section 11.2 on page 56

sbol-10218 ★ If a compliant Identified object has no version property, then its identity property MUST contain the same URI as its persistentIdentity property. Otherwise, the compliant object's identity property MUST contain a URI that begins with its persistentIdentity and is immediately followed by a delimiter ('/', '#', or ':') and its version.

Reference: Section 11.2 on page 56

sbol-10219 ★ The version property of a compliant Identified object that is not also a TopLevel object is REQUIRED to contain the same String as the version property of the compliant object's parent.

Reference: Section 11.2 on page 56

### Rules for the TopLevel class

sbol-10301 
✓ A TopLevel object MUST inherit all properties of the Identified class.

Reference: Section 7.5 on page 19

# Rules for the Sequence class

**sbol-10401** ✓ A Sequence MUST inherit all properties of the TopLevel class.

Reference: Section 7.6 on page 19

 $\textbf{sbol-10402} \ \ \, \overline{\textbf{V}} \qquad \text{The elements property of a Sequence is REQUIRED and MUST contain a String.}$ 

Reference: Section 7.6 on page 19

sbol-10403 

✓ The encoding property of Sequence is REQUIRED and MUST contain a URI.

Reference: Section 7.6 on page 19

sbol-10404 ▲ The encoding property of a Sequence MUST indicate how the elements property of the

Sequence is to be formed and interpreted.

Reference: Section 7.6 on page 19

sbol-10405 ▲ The elements property of a Sequence MUST be consistent with its encoding property.

Reference: Section 7.6 on page 19

sbol-10406 ▲ The encoding property of a Sequence MUST contain a URI from Table 1 if it is well-described

hy this IIRT

Reference: Section 7.6 on page 19

# Rules for the ComponentDefinition class

sbol-10501 

✓ A ComponentDefinition MUST inherit all properties of the TopLevel class.

Reference: Section 7.7 on page 21

Section A Validation Rules

sbol-10502	The types property of a ComponentDefinition is REQUIRED and MUST contain a non-empty set of URIs.  Reference: Section 7.7 on page 21
sbol-10503	The types property of a ComponentDefinition MUST NOT contain more than one URI from Table 2.  Reference: Section 7.7 on page 21
sbol-10504 ▲	Each URI contained by the types property of a ComponentDefinition MUST refer to an ontology term that describes the category of biochemical or physical entity that is represented by the ComponentDefinition.  Reference: Section 7.7 on page 21
sbol-10505 ▲	The types property of a ComponentDefinition MUST contain a URI from Table 2 if it is well-described by this URI.  Reference: Section 7.7 on page 21
sbol-10506 ▲	All URIs contained by the types property of a ComponentDefinition MUST refer to non-conflicting ontology terms.  Reference: Section 7.7 on page 21
sbol-10507   ✓	The roles property of a ComponentDefinition is OPTIONAL and MAY contain a set of URIs. Reference: Section 7.7 on page 21
sbol-10508 ▲	Each URI contained by the roles property of a ComponentDefinition MUST refer to an ontology term that clarifies the potential function of the ComponentDefinition in a biochemical or physical context.  Reference: Section 7.7 on page 21
sbol-10509 ▲	Each URI contained by the roles property of a ComponentDefinition MUST refer to an ontology term that is consistent with its types property.  Reference: Section 7.7 on page 21
sbol-10510 ▲	The roles property of a ComponentDefinition MUST contain a URI from Table 3 if it is well-described by this URI.  Reference: Section 7.7 on page 21
sbol-10511 ★	The roles property of a ComponentDefinition SHOULD only contain a URI provided in Table 3 if one of its types is cross-listed with this URI.  Reference: Section 7.7 on page 21
sbol-10512 ☑	The sequences property of a ComponentDefinition is OPTIONAL and MAY contain a set of URIs.  Reference: Section 7.7 on page 21
sbol-10513 ▲	Each URI contained by the sequences property of a ComponentDefinition MUST refer to a Sequence object.  Reference: Section 7.7 on page 21
sbol-10514 ▲	The Sequence objects referred to by the sequences property of a ComponentDefinition MUST be consistent with each other, such that well-defined mappings exist between their elements properties in accordance with their encoding properties.  Reference: Section 7.7 on page 21

The sequences property of a ComponentDefinition MUST NOT refer to Sequence objects

sbol-10515 A

with conflicting encoding properties. Reference: Section 7.7 on page 21

sbol-10516 ▲ If the sequences property of a ComponentDefinition refers to one or more Sequence objects, and one of the types of this ComponentDefinition comes from Table 2, then one of the Sequence objects MUST have the encoding that is cross-listed with this type in Table 1.

Reference: Section 7.7 on page 21

sbol-10517 ▲ If the sequences property of a ComponentDefinition refers to a Sequence with an encoding from Table 1, then the types property of the ComponentDefinition MUST contain the type from Table 2 that is cross-listed with this encoding in Table 1.

Reference: Section 7.7 on page 21

sbol-10518 ★ If a ComponentDefinition refers to more than one Sequence with the same encoding, then the elements of these Sequence objects SHOULD have equal lengths.

Reference: Section 7.7 on page 21

sbol-10519 

✓ The components property of a ComponentDefinition is OPTIONAL and MAY contain a set of Component objects.

Reference: Section 7.7 on page 21

sbol-10520 ★ If a ComponentDefinition in a ComponentDefinition-Component hierarchy refers to one or more Sequence objects, and there exist ComponentDefinition objects lower in the hierarchy that refer to Sequence objects with the same encoding, then the elements properties of these Sequence objects SHOULD be consistent with each other, such that well-defined mappings exist from the "lower level" elements to the "higher level" elements in accordance with their shared encoding properties. This mapping is also subject to any restrictions on the positions of the Component objects in the hierarchy that are imposed by the SequenceAnnotation or SequenceConstraint objects contained by the ComponentDefinition objects in the hierarchy.

Reference: Section 7.7 on page 21

sbol-10521 

✓ The sequenceAnnotations property of a ComponentDefinition is OPTIONAL and MAY contain a set of SequenceAnnotation objects.

Reference: Section 7.7 on page 21

sbol-10522 

✓ The sequenceAnnotations property of a ComponentDefinition MUST NOT contain two or more SequenceAnnotation objects that refer to the same Component.

Reference: Section 7.7 on page 21

sbol-10523 ★ If the sequences property of a ComponentDefinition refers to a Sequence with an IUPAC encoding from Table 1, then each SequenceAnnotation that includes a Range and/or Cut in the sequenceAnnotations property of the ComponentDefinition SHOULD specify a region on the elements of this Sequence.
Reference: Section 7.7 on page 21

sbol-10524 

✓ The sequenceConstraints property of a ComponentDefinition is OPTIONAL and MAY contain a set of SequenceConstraint objects.

Reference: Section 7.7 on page 21

### Rules for the ComponentInstance class

sbol-10601 

✓ A ComponentInstance MUST inherit all properties of the Identified class.

Reference: Section 7.7.1 on page 24

sbol-10602 

✓ The definition property of a ComponentInstance is REQUIRED and MUST contain a URI.

Reference: Section 7.7.1 on page 24

sbol-10603   ✓	The definition property of a ComponentInstance MUST NOT contain a URI reference to
	the ComponentDefinition that contains the ComponentInstance.
	Reference: Section 7.7.1 on page 24
sbol-10604 ▲	The URI contained by the definition property MUST refer to a ComponentDefinition object

sbol-10605 ▲ ComponentInstance objects MUST NOT form circular reference chains via their definition properties and parent ComponentDefinition objects.

Reference: Section 7.7.1 on page 24

sbol-10606 

✓ The mapsTos property of a ComponentInstance is OPTIONAL and MAY contain a set of MapsTo objects.

Reference: Section 7.7.1 on page 24

sbol-10607 

✓ The access property of a ComponentInstance is REQUIRED and MUST contain a URI from Table 4

Reference: Section 7.7.1 on page 24

Reference: Section 7.7.1 on page 24

# Rules for the Component class

sbol-10701 ✓ A Component MUST inherit all properties of the ComponentInstance class. Reference: Section 7.7.1 on page 24

### Rules for the MapsTo class

- sbol-10801 
  ✓ A MapsTo MUST inherit all properties of the Identified class.

  Reference: Section 7.7.3 on page 26
- sbol-10802 

  ✓ The local property of a MapsTo is REQUIRED and MUST contain a URI.

  Reference: Section 7.7.3 on page 26
- sbol-10803 

  ✓ If a MapsTo is contained by a Component in a ComponentDefinition, then the local property of the MapsTo MUST refer to another Component in the ComponentDefinition.

  Reference: Section 7.7.3 on page 26
- sbol-10804 

  If a MapsTo is contained by a FunctionalComponent or Module in a ModuleDefinition, then the local property of the MapsTo MUST refer to another FunctionalComponent in the ModuleDefinition.

  Reference: Section 7.7.3 on page 26
- sbol-10805 

  ✓ The remote property of a MapsTo is REQUIRED and MUST contain a URI.

  Reference: Section 7.7.3 on page 26
- sbol-10806 ▲ The remote property of a MapsTo MUST refer to a ComponentInstance.

  Reference: Section 7.7.3 on page 26
- sbol-10807 ▲ The ComponentInstance referred to by the remote property of a MapsTo MUST have an access property that contains the URI http://sbols.org/v2#public.

  Reference: Section 7.7.3 on page 26
- sbol-10808 ▲ If a MapsTo is contained by a ComponentInstance, then the remote property of the MapsTo MUST refer to a Component in the ComponentDefinition that is referenced by the definition property of the ComponentInstance.

  Reference: Section 7.7.3 on page 26

sbol-10809 ▲	If a MapsTo is contained by a Module, then the remote property of the MapsTo MUST refer to a FunctionalComponent in the ModuleDefinition that is referenced by the definition property of the Module.  Reference: Section 7.7.3 on page 26
sbol-10810   ✓	The refinement property of a MapsTo is REQUIRED and MUST contain a URI from Table 5. Reference: Section 7.7.3 on page 26
sbol-10811 ▲	If the refinement property of a MapsTo contains the URI http://sbols.org/v2#verifyIdentithen the ComponentInstance objects referred to by local and remote properties of the MapsTo MUST refer to the same ComponentDefinition via their definition properties. Reference: Section 7.7.3 on page 26
Rules for the Se	equenceAnnotation class
sbol-10901	A SequenceAnnotation MUST inherit all properties of the Identified class. Reference: Section 7.7.4 on page 29
sbol-10902   ✓	The locations property of a SequenceAnnotation is REQUIRED and MUST contain a non- empty set of Location objects. Reference: Section 7.7.4 on page 29
sbol-10903 ★	The Location objects contained by the locations property of a single SequenceAnnotation SHOULD NOT specify overlapping regions.  Reference: Section 7.7.4 on page 29
sbol-10904   ✓	The component property is OPTIONAL and MAY contain a URI reference to a Component. Reference: Section 7.7.4 on page 29
sbol-10905   ✓	The Component referenced by the component property of a SequenceAnnotation MUST be contained by the ComponentDefinition that contains the SequenceAnnotation.  Reference: Section 7.7.4 on page 29
Rules for the Lo	ocation class
sbol-11001	A Location MUST inherit all properties of the Identified class. Reference: Section 7.7.5 on page 30
sbol-11002	The orientation property of a Location is OPTIONAL and MAY contain a URI from Table 6. Reference: Section 7.7.5 on page 32
Rules for the Ra	ange class
sbol-11101	A Range MUST inherit all properties of the Location class. Reference: Section 7.7.5 on page 31
sbol-11102    ✓	The start property of a Range is REQUIRED and MUST contain an Integer greater than zero. Reference: Section 7.7.5 on page 31
sbol-11103   ✓	The end property of a Range is REQUIRED and MUST contain an Integer greater than zero. Reference: Section 7.7.5 on page 31
sbol-11104   ✓	The value of the end property of a Range MUST be greater than or equal to the value of its start property.

Reference: Section 7.7.5 on page 31

### Rules for the Cut class

sbol-11201 

✓ A Cut MUST inherit all properties of the Location class.

Reference: Section 7.7.5 on page 31

The at property is REQUIRED and MUST contain an Integer greater than or equal to zero. Reference: Section 7.7.5 on page 31

### Rules for the GenericLocation class

shol-11301 

✓ A GenericLocation MUST inherit all properties of the Location class. Reference: Section 7.7.5 on page 32

# Rules for the SequenceConstraint class

- sbol-11401 

  ✓ A SequenceConstraint MUST inherit all properties of the Identified class. Reference: Section 7.7.6 on page 32
- The subject property is REQUIRED and MUST contain a URI reference to a Component. Reference: Section 7.7.6 on page 32
- The Component referenced by the subject property of a SequenceConstraint MUST be contained by the ComponentDefinition that contains the SequenceConstraint. Reference: Section 7.7.6 on page 32
- The object property is REQUIRED and MUST contain a URI reference to a Component. Reference: Section 7.7.6 on page 32
- The Component referenced by the object property of a SequenceConstraint MUST be contained by the ComponentDefinition that contains the SequenceConstraint. Reference: Section 7.7.6 on page 32
- The object property of a SequenceConstraint MUST NOT refer to the same Component as sbol-11406 √ the subject property of the SequenceConstraint. Reference: Section 7.7.6 on page 32
- sbol-11407 

  ✓ The restriction property is REQUIRED and MUST contain a URI. Reference: Section 7.7.6 on page 32
- shol-11408 A The URI contained by the restriction property of a SequenceConstraint MUST indicate the type of structural restriction on the relative, sequence-based positions or orientations of the Component objects referred to by the subject and object properties of the SequenceConstraint.

Reference: Section 7.7.6 on page 32

- sbol-11409 A If the restriction property of a SequenceConstraint contains the URI http://sbols.org/ v2#precedes, then the position of the Component referred to by the subject property of the SequenceConstraint MUST precede that of the Component referred to by its object property. Reference: Section 7.7.6 on page 32
- sbol-11410 A If the restriction property of a SequenceConstraint contains the URI http://sbols.org/ v2#sameOrientationAs, then the orientation of the Component referred to by the subject property of the SequenceConstraint MUST be the same as that of the Component referred to by its object property.

Reference: Section 7.7.6 on page 32

sbol-11411 A If the restriction property of a SequenceConstraint contains the URI http://sbols. org/v2#oppositeOrientationAs, then the orientation of the Component referred to by the

	subject property of the SequenceConstraint MUST be opposite that of the Component re-
	ferred to by its object property.  Reference: Section 7.7.6 on page 32
sbol-11412 ★	The URI contained by the restriction property SHOULD come from Table 7. Reference: Section 7.7.6 on page 32
Rules for the Mo	del class
sbol-11501	A Model MUST inherit all properties of the TopLevel class. Reference: Section 7.8 on page 34
sbol-11502    ✓	The source property is a REQUIRED and MUST contain a URI. Reference: Section 7.8 on page 34
sbol-11503 ▲	The URI contained by the source property of a Model MUST specify the location of the model's source file.  Reference: Section 7.8 on page 34
sbol-11504 <b>√</b>	The language property is REQUIRED and MUST contain a URI. Reference: Section 7.8 on page 34
sbol-11505 🔺	The URI contained by the language property of a Model MUST specify the language in which the model is encoded.  Reference: Section 7.8 on page 34
sbol-11506 ▲	The language property of a Model MUST contain a URI from Table 8 if it is well-described by this URI.  Reference: Section 7.8 on page 34
sbol-11507 ★	The language property of a Model SHOULD contain a URI that refers to a term from the EDAM ontology.  Reference: Section 7.8 on page 34
sbol-11508 ☑	The <b>framework</b> property is REQUIRED and MUST contain a URI. Reference: Section 7.8 on page 34
sbol-11509 ▲	The URI contained by the framework property of a Model MUST specify the modeling framework of the model.  Reference: Section 7.8 on page 34
sbol-11510 ▲	The <b>framework</b> property of a Model MUST contain a URI from Table 9 if it is well-described by this URI.  Reference: Section 7.8 on page 34
sbol-11511 ★	The <b>framework</b> property SHOULD contain a URI that refers to a term from the modeling framework branch of the SBO.  Reference: Section 7.8 on page 34
Rules for the Mo	duleDefinition class
sbol-11601 ☑	A ModuleDefinition MUST inherit all properties of the TopLevel class. Reference: Section 7.9 on page 35
sbol-11602   ✓	The roles property is OPTIONAL and MAY contain a set of URIs.

Reference: Section 7.9 on page 35

sbol-11603 ▲	Each URI contained by roles property of a ModuleDefinition MUST refer to a resource that clarifies the intended function of the ModuleDefinition.  Reference: Section 7.9 on page 35	1 2 3
sbol-11604   ✓	The modules property OPTIONAL and MAY contain a set of Module objects.  Reference: Section 7.9 on page 35	4 5
sbol-11605    ✓	The interactions property is OPTIONAL and MAY contain a set of Interaction objects. Reference: Section 7.9 on page 35	6 0
sbol-11606	The functionalComponents property is OPTIONAL and MAY contain a set of FunctionalCompo objects.  Reference: Section 7.9 on page 35	
sbol-11607   ✓	The models property is OPTIONAL and MAY contain a set of URIs.  Reference: Section 7.9 on page 35	
sbol-11608 🔺	Each URI contained by the models property of a ModuleDefinition MUST refer to a Model. Reference: Section 7.9 on page 35	11 12 13 14
Rules for the Mo	dule class	15
sbol-11701 ☑	A Module MUST inherit all properties of the Identified class. Reference: Section 7.9.1 on page 37	
sbol-11702   ✓	The definition property of a Module is REQUIRED and MUST contain a URI. Reference: Section 7.9.1 on page 37	18
sbol-11703   ✓	The URI contained by the definition property of Module MUST refer to a ModuleDefinition. Reference: Section 7.9.1 on page 37	20 0
sbol-11704      ✓	The definition property of a Module MUST NOT contain a URI reference to the ModuleDefinit that contains the Module. sbol-11705 ▲	Module objects MUST NOT form circular reference chains via their definition properties and parent ModuleDefinition objects.  Reference: Section 7.9.1 on page 37	tegrative Bioi
sbol-11706 ☑	The mapsTos property is OPTIONAL and MAY contain a set of MapsTo objects. Reference: Section 7.9.1 on page 37	ss ss urnal of In
Rules for the Fu	nctionalComponent class	by Jo
sbol-11801   ✓	A FunctionalComponent MUST inherit all properties of the ComponentInstance class. Reference: Section 7.7.1 on page 24	Published
sbol-11802 ☑	The direction property of a FunctionalComponent is REQUIRED and MUST contain a URI from Table 10.  Reference: Section 7.9.2 on page 38	Copyright 2015 The Author(s). Published by Journal
Rules for the Inte	eraction class	% 015 T
sbol-11901   ✓	An Interaction MUST inherit all properties of the Identified class. Reference: Section 7.9.3 on page 39	% & constant 2
sbol-11902   ✓	The types property of an Interaction is REQUIRED and MUST contain a non-empty set of URIs.	39 40
	Reference: Section 7.9.3 on page 39	41

Each URI contained by the types property of an Interaction MUST refer to an ontology term that describes the behavior represented by the Interaction.

Reference: Section 7.9.3 on page 39

sbol-11904 ▲ All URIs contained by the types property of an Interaction MUST refer to non-conflicting ontology terms.

Reference: Section 7.9.3 on page 39

sbol-11905 ★ A least one URI contained by the types property of an Interaction SHOULD refer to a term from the occurring entity relationship branch of the SBO.

Reference: Section 7.9.3 on page 39

sbol-11906 

✓ The participations property of an Interaction is OPTIONAL and MAY contain a set of Participation objects.

Reference: Section 7.9.3 on page 39

# Rules for the Participation class

sbol-12001 
✓ A Participation MUST inherit all properties of the Identified class.

Reference: Section 7.9.4 on page 41

sbol-12002 

✓ The participant property of a Participation is REQUIRED and MUST contain a URI reference to a Functional Component.

Reference: Section 7.9.4 on page 41

sbol-12003 

✓ The FunctionalComponent referenced by the participant property of a Participation MUST be contained by the ModuleDefinition that contains the Interaction which contains the Participation.

Reference: Section 7.9.4 on page 41

sbol-12004 

✓ The roles property of an Participation is OPTIONAL and MAY contain a set of URIs.

Reference: Section 7.9.4 on page 41

sbol-12005 ▲ Each URI contained by the roles property of an Participation MUST refer to an ontology term that describes the behavior represented by the Participation.

Reference: Section 7.9.4 on page 41

sbol-12006 ▲ All URIs contained by the roles property of an Participation MUST refer to non-conflicting ontology terms.

Reference: Section 7.9.4 on page 41

sbol-12007 ★ A least one role in the set of roles SHOULD be a URI from the participant role branch of the SBO.

Reference: Section 7.9.4 on page 41

### Rules for the Collection class

sbol-12101 
✓ A Collection MUST inherit all properties of the TopLevel class.

Reference: Section 7.10 on page 42

sbol-12102 

✓ The members property of a Collection is OPTIONAL and MAY contain a set of URIs.

Reference: Section 7.10 on page 42

sbol-12103 ▲ Each URI contained by the members property of a Collection MUST reference a TopLevel object.

Reference: Section 7.10 on page 42

#### Rules for the Annotation class

sbol-12201 

✓ The name property of an Annotation is REQUIRED and MUST contain a QName.

Reference: Section 7.11 on page 43

sbol-12202 

✓ The value property of an Annotation is REQUIRED and MUST contain an AnnotationValue.

Reference: Section 7.11 on page 43

sbol-12203 
✓ An AnnotationValue MUST be a literal (a String, Integer, Double, or Boolean), URI, or a NestedAnnotations object.

Reference: Section 7.11 on page 43

The post of ONe are property of a Neet of Appet at i one object is REOLINEED and MUST.

 $\textbf{sbol-12204} \ \ \, \overrightarrow{\hspace{1cm}} \quad \text{The nestedQName property of a NestedAnnotations object is REQUIRED and MUST contain a QName.}$ 

Reference: Section 7.11 on page 43

sbol-12205 

✓ The nestedURI property of a NestedAnnotations object is REQUIRED and MUST contain a IRT

Reference: Section 7.11 on page 43

sbol-12206 

✓ The annotations property of a NestedAnnotations object is OPTIONAL and MAY contain a set of Annotation objects.

Reference: Section 7.11 on page 43

# Rules for the GenericTopLevel class

sbol-12301 
✓ A GenericTopLevel object MUST inherit all properties of the TopLevel class.

Reference: Section 7.11.2 on page 45

sbol-12302 

✓ The rdfType property of a GenericTopLevel object is REQUIRED and MUST contain a QName.

Reference: Section 7.11.2 on page 45

# **B.1.3** Serializing SequenceConstraint Objects

This example shows the serialization of SequenceConstraint between two Component objects in a composite promoter ComponentDefinition. In the example, the promoter ComponentDefinition has two sub-Components that instantiate the ComponentDefinition objects for a core promoter region and and a binding site. The SequenceConstraint specifies that the core promoter region precedes the binding site.

Section B.1 Simple Examples

```

</rdf:RDF>
```

# B.1.9 Serializing Collection Objects

This example shows the serialization of a Collection. This Collection represents a library of promoters.

# **B.2** Complex Examples

# **B.2.1 PoPS Receiver**

This example shows the serialization of the PoPS Receiver device designed by Canton and co-workers Canton et al. (2008). In particular, this example includes the serialization of a ComponentDefinition that composes five Component objects to define the structure of a detector for the cell-cell signaling molecule  $30C_6HSL$ . The five components are arranged in a sequence: first come four Component objects that together implement constitutive expression of the LuxR protein, which in turn responds to  $30C_6HSL$ : a constitutive promoter, 5'UTR, coding sequence for LuxR, and terminator. Finally, after these objects comes the Component object for the pLuxR promoter, which is activated in the presence of LuxR and  $30C_6HSL$ . Complete details of the device can be found in the cited paper and also at http://parts.igem.org/Part:BBa\_F2620.

Section B.2 Complex Examples

# **B.2.2** Toggle Switch

This example shows the serialization of the ComponentDefinition and ModuleDefinition objects for a LacI/TetR toggle switch similar to those constructed in Gardner et al. (2000). This design is essentially similar to the one presented in Section 9, except that it uses some alternate groupings in how the total design is built up out of smaller
